We would also note that the net investment return used to demonstrate Section 7 compliance should be net of asset-based charges and therefore would include any explicit fees as well as any market value adjustments. Therefore, the 7% in Model 250 would be grossed up for variable annuity asset-based charges and then reduced for the aforementioned items or utilize average returns by index and then reduce for the aforementioned items.

The ACLI and the CAI appreciate the opportunity to comment on the Exposure and we urge continued discussion and collaboration to develop an AG that satisfies our shared objective - and well stated principle - of equity to both contract holders and insurers in the design and administration of RILA products. Further, the ACLI and CAI appreciate the NAIC’s stated desire to minimize any market disruption that could occur as a result of this AG. In that spirit, we are hopeful that the NAIC will continue to work with the ACLI and CAI on transition timing that appropriately reflects the practical realities of implementation as the AG is finalized.

Respectfully submitted,

Proposed Actuarial Guideline on ILVAs from the American Council of Life Insurers (ACLI) and Committee of Annuity Insurers (CAI) (May 2, 2022)

Actuarial Guideline ILVA Nonforfeiture Requirements for Index Linked Variable Annuity Products Supported by Non-Unitized Accounts

**Background**

The purpose of this guideline is to specify the conditions under which an Index-Linked Variable Annuity (ILVA) is consistent with the definition of a variable annuity and exempt from Model 805 and specify nonforfeiture requirements consistent with variable annuities.

A number of insurers have developed and are issuing annuity products with credits based on the performance of an index with caps on returns, participation rates, spreads or margins, or other crediting elements, which include limitations on loss such as a floor or a buffer. These products are not unitized and do not invest directly in the assets whose performance forms the basis for the credits. However, unlike traditional non-variable indexed annuities, these annuities may reflect negative index returns.

There is no established terminology for these annuity products. These products go by several names, including structured annuities, registered index-linked annuities (RILA), or index-linked variable annuities, among others. This guideline refers to these products as index-linked variable annuities (ILVA).

Variable annuities are exempted from the scope of NAIC Model 805, *Standard Nonforfeiture Law for Individual Deferred Annuities*, however, NAIC Model 805 does not define the term "variable annuity".

NAIC Model 250, *Variable Annuity Model Regulation*, defines variable annuities as "contracts that provide for annuity benefits that vary according to the investment experience of a separate account" Section 7B of NAIC Model 250 provides that "to the extent that a variable annuity contract provides benefits that do not vary in accordance with the investment performance of a separate account" the contract shall satisfy the requirements of the NAIC Model 805.

The application of the NAIC Model 250 to a traditional variable annuity with unitized values is straightforward. The unitized feature provides an automatic linkage between annuity values and the investment experience of a separate account. Daily values (market values of the separate account assets) are the basis of all the benefits, including surrender values.

The fact that ILVA products are not unitized means they do not have values determined directly by the market prices of the underlying assets. Therefore, this guideline sets forth
ACLI and CAI Proposed AG on ILVAs (Redline)
principles and requirements for determining values, including death benefit, withdrawal amount, annuitization amount or surrender values, such that an ILVA is considered a variable annuity and thereby exempt from Model 805. An ILVA that does not comply with the principles and requirements of this guideline is not considered a variable annuity and therefore is subject to Model 805.

Drafting Note: This guideline interprets the term “variable annuity” for purposes of exemption from Model 805. It is not intended to modify or interpret the definition of a variable annuity under Model 250 or other Model Regulations.

Scope

This guideline applies to any index-linked annuity exempt from the NAIC Model 805 on the basis that it is a variable annuity provided through non-unitized separate account(s) and includes index-linked crediting features that are built into policies or contracts (with or without unitized subaccounts) or added to such by rider, endorsement, or amendment.

This guideline does not apply to an annuity contract or a subaccount of an annuity contract that is subject to the requirements of NAIC Model 805, Standard Nonforfeiture Law for Individual Deferred Annuities.

Principles

This guideline is based on the following principles:

1. There exists a package of derivative assets that replicates the index credits provided by an index strategy at the end of an index term.
2. The value of the package of derivative assets can be determined daily using assumptions consistent with observable market inputs and parameters, whenever possible.
3. Interim Values defined in the contract provide equity to both the contract holder and the company where the Interim Values are consistent with the value of the Hypothetical Portfolio over the index term.
4. Market Value Adjustments that reflect changes in the value of hypothetical fixed income assets due to interest rate and/or credit spread movements are allowed. They may be applied in the Interim Value calculation or at the contract level.

Definitions

“Derivative Asset Proxy” means a package of hypothetical derivative assets designed to replicate credits provided by an Index Strategy at the end of an Index Term.

“Discount Rate” means the rate used to calculate the value of the Fixed Income Asset Proxy during the Index Strategy Term. This rate may be a simple or compound rate, may be expressed as a risk-free rate plus a spread, or may be an implied rate used to amortize the initial Derivative Asset Proxy value over the Index Strategy Term as described in the actuarial certification.
“Fixed Income Asset Proxy” is a hypothetical fixed income asset.

“Hypothetical Portfolio” means a hypothetical portfolio composed of a Fixed Income Asset Proxy and a Derivative Asset Proxy.

“Interim Value” mean the Strategy Value at any time other than the start date and end date of an Index Term.

“Index Strategy” means a method used to determine index credits with specified index-or indices or observable benchmarks and cap, buffer, participation rate, spread, margin or other index crediting elements.

“Index Strategy Base” means the notional amount used to determine index credits that does not change throughout the Index Term except for withdrawals, transfers, deposits, and any explicit charges.

“Index Strategy Term” means the period of time from the term start date to the term end date over which an index change and index credit is determined. A term may end due to product and/or crediting features (e.g., a specified end date, a “lock-in” feature, etc.)

“Strategy Value” means the value, attributable to an Index Strategy, used in determining values including death benefit, withdrawal amount, annuitization amount or surrender values.

Text

Index Strategy Base must equal the Strategy Value at an Index Term start date.

The value of the Fixed-Income Asset Proxy:

a. At the beginning of the Index Strategy Term equals the Index Strategy Base less the Derivative Asset Proxy value; and
b. At any point in time between the Index Strategy Term start date and the end of the Index Strategy Term, is determined by discounting the Index Strategy Base for the remainder of the Index Strategy Term at the Discount Rate. This may also be subject to a Market Value Adjustment as outlined in Principle 4; and
b.c. At the end of the Index Strategy Term equals the Index Strategy Base; and

a. Earns interest at a level rate.

The value of the Hypothetical Portfolio at any time is the sum of the Fixed-Income Asset Proxy value and the Derivative Asset Proxy value less a provision for the cost of unwinding the hedge positions not to exceed 10 bps designed to address the reasonable cost of unwinding the Derivative Asset Proxy. Such a provision may be either applied to all circumstances or take the form of a more targeted adjustment applicable only in specific circumstances in which the risk of unwinding Derivative Asset Proxy may be heightened as described in the actuarial certification.
Contracts in the scope of this guideline must provide Interim Values that are consistent with the value of the Hypothetical Portfolio over the Index Strategy Term.

If a contract provides Interim Values determined using a methodology other than a Hypothetical Portfolio methodology as described in this guideline, the company must demonstrate that the contractually defined Interim Values will be materially consistent with the Interim Values that would be produced using the Hypothetical Portfolio methodology for each combination of Index Strategy and Index Strategy Term. The company may choose to demonstrate under a reasonable number of economic stochastic economic scenarios or a set of deterministic scenarios.

Drafting Note: Acceptable One example of an acceptable demonstration of materially consistent would show that at intermediate points during the Index Strategy Term, the expected value of Interim Values produced using the Hypothetical Portfolio minus the expected value of contractually defined Interim Values is at most 5% of the Index Strategy Base. The expected value will be defined as the average of the Interim Values over the set of economic scenarios over which consistency should to be demonstrated is yet to. Acceptable stochastic economic scenarios may be determined. Considerations are from the Academy Interest Rate Generator and/or defined any other reasonable real-world economic scenario generator where the generator and any key additional assumptions used to value the Derivative Asset Proxy are described in the actuarial certification. If deterministic scenarios are used, these may include shocks that trigger Index Strategy parameters including but not limited to caps, floors, and buffers.

At the time of filing, the company must provide an actuary’s certification that the provisions of this guideline are being met.

Assumptions used to value the Derivative Asset Proxy including yields, implied volatility, risk-free rate, and dividend yield, and other parameters required for the valuation method of the derivatives must be consistent with the observable market prices of derivative assets, whenever possible.

ILVA nonforfeiture benefits must comply with Section 7 of Model 250 (other than Section 7.B) with net investment return (reflecting any Market Value Adjustment and any explicit fees) consistent with the requirements for determining Interim Values in this guideline.

The company (or actuary) must describe the Fixed Income Asset Proxy and the Derivative Asset Proxy and with the assumptions used to calculate these values at any time. (including the reasonable cost of unwinding the Derivative Asset Proxy).

ACLI and CAI Proposed AG on ILVAs (Clean)
Proposed Actuarial Guideline on ILVAs from the American Council of Life Insurers (ACLI) and Committee of Annuity Insurers (CAI) (May 2, 2022)

Actuarial Guideline ILVA
Nonforfeiture Requirements for Index Linked Variable Annuity Products Supported by Non-Unitized Accounts

Background

The purpose of this guideline is to specify the conditions under which an Index-Linked Variable Annuity (ILVA) is consistent with the definition of a variable annuity and exempt from Model 805 and specify nonforfeiture requirements consistent with variable annuities.

A number of insurers have developed and are issuing annuity products with credits based on the performance of an index with caps on returns, participation rates, spreads or margins, or other crediting elements, which include limitations on loss such as a floor or a buffer. These products are not unitized and do not invest directly in the assets whose performance forms the basis for the credits. However, unlike traditional non-variable indexed annuities, these annuities may reflect negative index returns.

There is no established terminology for these annuity products. These products go by several names, including structured annuities, registered index-linked annuities (RILA), or index-linked variable annuities, among others. This guideline refers to these products as index-linked variable annuities (ILVA).

Variable annuities are exempted from the scope of NAIC Model 805, *Standard Nonforfeiture Law for Individual Deferred Annuities*, however, NAIC Model 805 does not define the term "variable annuity".

NAIC Model 250, *Variable Annuity Model Regulation*, defines variable annuities as “contracts that provide for annuity benefits that vary according to the investment experience of a separate account” Section 7B of NAIC Model 250 provides that "to the extent that a variable annuity contract provides benefits that do not vary in accordance with the investment performance of a separate account” the contract shall satisfy the requirements of the NAIC Model 805.

The application of the NAIC Model 250 to a traditional variable annuity with unitized values is straightforward. The unitized feature provides an automatic linkage between annuity values and the investment experience of a separate account. Daily values (market values of the separate account assets) are the basis of all the benefits, including surrender values.

The fact that ILVA products are not unitized means they do not have values determined directly by the market prices of the underlying assets. Therefore, this guideline sets forth
principles and requirements for determining values, including death benefit, withdrawal amount, annuitization amount or surrender values, such that an ILVA is considered a variable annuity and thereby exempt from Model 805. An ILVA that does not comply with the principles and requirements of this guideline is not considered a variable annuity and therefore is subject to Model 805.

Drafting Note: This guideline interprets the term “variable annuity” for purposes of exemption from Model 805. It is not intended to modify or interpret the definition of a variable annuity under Model 250 or other Model Regulations.

Scope

This guideline applies to any index-linked annuity exempt from the NAIC Model 805 on the basis that it is a variable annuity provided through non-unitized separate account(s) and includes index-linked crediting features that are built into policies or contracts (with or without unitized subaccounts) or added to such by rider, endorsement, or amendment.

This guideline does not apply to an annuity contract or a subaccount of an annuity contract that is subject to the requirements of NAIC Model 805, Standard Nonforfeiture Law for Individual Deferred Annuities.

Principles

This guideline is based on the following principles:

1. There exists a package of derivative assets that replicates the index credits provided by an index strategy at the end of an index term.
2. The value of the package of derivative assets can be determined using assumptions consistent with observable market inputs and parameters, whenever possible.
3. Interim Values defined in the contract provide equity to both the contract holder and the company where the Interim Values are consistent with the value of the Hypothetical Portfolio over the index term.
4. Market Value Adjustments that reflect changes in the value of hypothetical fixed income assets due to interest rate and/or credit spread movements are allowed. They may be applied in the Interim Value calculation or at the contract level.

Definitions

“Derivative Asset Proxy” means a package of hypothetical derivative assets designed to replicate credits provided by an Index Strategy at the end of an Index Term.

“Discount Rate” means the rate used to calculate the value of the Fixed Income Asset Proxy during the Index Strategy Term. NAIC Index-Linked Variable Annuity Subgroup
Peter Weber, Chair & Tomasz Serbinowski, Vice-Chair

Re: Actuarial Guideline ILVA: Nonforfeiture Requirements for Index Linked Variable Annuity Products Supported by Non-Unitized Accounts (“Exposure”)

Dear Mr. Weber and Mr. Serbinowski:

On behalf of our members, the Insured Retirement Institute, Inc. (“IRI”)¹ appreciates the opportunity to comment on the Exposure put forth by the Index-Linked Variable Annuity Subgroup (“Subgroup”). We appreciate the work of the Subgroup and believe that this Exposure has been significantly improved upon; however, we are recommending some additional edits and feedback to ensure that the Exposure encompasses products currently in the market and does not impede product innovation.

IRI received and reviewed the comments on the Exposure by the American Council of Life Insurers (“ACLI”) and the Committee of Annuity Insurers (“CAI”), dated May 2, 2022. With ACLI and CAI’s permission, IRI shared this letter with our membership.

Following discussion with our members, IRI supports ACLI and CAI’s comments with respect to its requests and recommendations regarding the Exposure, including the mark-up of the Exposure that is being put forth for consideration.

Overall, our members support the allowance of different approaches to determining values as this leads to product innovation and supports consumer choice when selecting a product that best achieves their financial goals. We appreciate that this second draft of the Actuarial Guideline takes this into account by being more principles-based, but we do support the changes and recommendations put forth by ACLI and CAI in their mark-up of the Exposure. As such, we respectfully request that the Subgroup consider the recommendations put forth in ACLI’s and CAI’s comment letter.

On behalf of IRI and our members, thank you again for the opportunity to provide these comments. We would be happy to discuss further with you and look forward to continued collaboration and partnership with the Subgroup.

¹ IRI is the leading association for the entire supply chain of insured retirement strategies, including life insurers, asset managers, and distributors such as broker-dealers, banks, and marketing organizations. IRI members account for more than 95 percent of annuity assets in the U.S., the top 10 distributors of annuities ranked by assets under management and are represented by financial professionals serving millions of Americans. IRI champions retirement security for all through leadership in advocacy, awareness, research, and the advancement of digital solutions within a collaborative industry community.

RE: Comments on the Exposure of Actuarial Guideline ILVA – Nonforfeiture Requirements for Index Linked Variable Annuity Products Supported by Non-Unitized Accounts (PAG2)

Mr. Weber,

As a commenter not employed by a life insurer, or affiliated with a regulatory body, or a trade association, I am very grateful for your consideration of my comments. Having no actuarial training I ask that you please excuse the general nature of my assertions. I would like to present a responsible marketer’s perspective. By way of background, as President of CompEdge Financial, I have held a life insurance license since 1982, have supervised Broker/Dealer Branch Office regulated by FINRA, served over 10 years as the President and Chief Compliance Officer of a SEC-registered Registered Investment Adviser firm, and operate an Independent Marketing Organization.

The establishment of a protocol to report interim values within ILVA’s is an important task and I appreciate the comments thus far. My concern is that the difficulty in creating the methodology, and the disagreement to date, centers not on what is fair to the buying public but what is easiest and least transparent for the carriers.

While respecting the narrow scope of this subgroup it is important to consider broader contexts to facilitate decision making.

Defined-Outcome Product Background
Hysterically, the objective of a structured investment is to combine non-correlated assets in such a way that they form a defined set of possible outcomes at the date of purchase. Holding various long and short positions in index options is a traditional method of accomplishing this goal. The result is a portfolio designed to exist for a limited period of time in markets where a buy/hold equity strategy presents unacceptable downside risk – an alternative strategy. Often these accounts create a scheme where regardless of market activity the client is not subject to first-dollar losses down to a designed percentage, or a buffer. Typically, private investors and professionals use nearly 100% of the available seed cash in the strategy (minus 1-3% set aside
for expenses and profit). This ensures interim values of the account are easily discernable in real time in the trust or fund based on the market prices of the options employed.

Insurers saw the opportunity to accomplish similar defined outcomes with a slightly different option strategy. Their strategy allows them to create a buffer/cap product while not allocating all the premium to the strategy. In fact, many of the buffer/cap options seen now can be accomplished with no net premium spent on behalf of the client at all.

When done in an annuity chassis, minimal holdings in option positions are held in a separate account while well over 90% of the premium is available for use in the General Account for the carrier’s investment in long-term assets, to pay concessions to Broker/Dealers, and provide company profits. This is essentially an interest-free loan of the client’s annuity premium to the insurer as collateral should the buffer ever fail, and someone must clean up the mess. There is a cost to this alternative to the investor as it is not possible to achieve the same upside cap available otherwise without the carrier allocating a significant portion of those funds to enhance caps.

**Oversight of Distribution Partners**

Because these products are registered, their distribution falls to Broker/Dealers and their Registered Representatives. B/D’s have attempted to insert themselves in the revenue stream of Fixed Indexed Annuity sales for a decade. FINRA requires the B/D to supervise all the RR’s recommendations but, as fixed products, the independent RR is free to sell FIAs through any number of other outlets. All attempts to address this have failed. ILVA’s give B/D’s a successful new revenue stream with all the flavor of an FIA yet registered for distribution only through B/D’s.

The SEC Regulation Best Interest (RegBI) details the duties of B/D’s and their supervised representatives. RegBI stipulates they must available alternatives to a recommendation, and to consider all relevant costs and limitations. The lack of transparency in the assets held in ILVA’s makes fulfilling this duty impossible. It is the only SEC-registered product sold by prospectus that does not detail where every dollar of the client’s money goes.

A new term might help identify and compare the true value of each carrier’s product. How much money is the carrier allocating to the buffer strategy? A buffer strategy can be accomplished in any brokerage account with no net cost. In other words, the premiums both spent and received on options to produce the strategy can net each other out. This would provide a low upside cap, however. To be competitive carriers must offer higher caps and would have to subsidize the strategy with earnings they would rather bank in the General Account. If we are going to use hypothetical values elsewhere, can we create a concept called the “Option Budget Allocation” expressed as a percentage of the client’s premium or annuity value used to enhance caps? My observation has been that this is roughly equal to the percentage the carrier is crediting in the product’s fixed account. If so, contract holders are
incurring large opportunity costs on their premium while only receiving an economic benefit in the neighborhood of 1%/year on their capital.

Carriers insist ILVA’s are spread products and their expenses cannot be quantified. However, they are quick to point out the “spread” concept is not to be confused with the traditional use of the word in an index strategy where the spread percentage is clearly stated. The best of both worlds. Some accountability is needed here.

FINRA is charged with ensuring B/Ds are complying with the SEC’s RegBI and have long-standing requirements that RR’s avoid misstatements or omissions of material facts. The marketing departments of ILVA providers do not seem to respect the difficulty advisors have in fulfilling these obligations given the materials provided for sales and the talking points of their wholesalers. Let’s examine some of those possible omissions and misrepresentations:

1) With few honorable exceptions, carriers claim that they “absorb” all loses from the original principal to the bottom of the buffer. In fact, there is no insurance element to that event whatsoever. Clearly carriers are not risking surplus equal to 10, 15, or 25% of annuity values. There is simply no economic activity as no option is in play in the buffer zone.

2) Sales brochures talk about the upside of the index but fail to prominently mention it is only the price movement of the index being credited and dividends are not included. A fair comparison of outcomes in all markets that included dividends in client brochures would allow more informed decisions.

3) Most insurers offer a 6-year term for each strategy. That is simply too long a term to make any sort of market judgement and the options market reflects that. A 6-year bucket with a 300% cap is virtually uncapped, like an S&P 500 ETF. However, the value of a 10% buffer in an ILVA would be covered by compounded dividends over 6 years in an Index ETF without a buffer. An outright purchase of an S&P 500 ETF will have the same risk characteristics - no ILVA value add.

4) “No Fees” - Many carriers prominently and repeatedly claim to charge no fees in their materials. While there may be no additional out-of-pocket fee this is dangerously misleading. As discussed, the opportunity cost of not investing elsewhere is substantial. If there are no fees, where is the discussion on how the company profits? The implication is that they are free. At the time of sale B/Ds require RRs to complete forms detailing the fees, policy charges, surrender charges, and investment expense percentages on every variable annuity sold. Variable annuities carriers simply must provide that information to protect their distributors. Expenses should be detailed.

5) With no discernable insurance element to a variable tax-deferred product FINRA has held that they are not suitable for funding IRA’s or other qualified rollovers since tax-deferral is already present and the underlying investment can be obtained with
lower expenses. Minimal death benefit options and poor living benefit riders may not be enough to overcome this logic.

6) An available alternative to an ILVA is any UIT employing a similar buffer. For any given buffer the caps on UIT’s tend to exceed the ILVA. There are notable exceptions. Carriers that charge a fee to enhance caps or participation rates can outperform with active recommendations by the RR and an astute client.

Interim Value Calculation Debate

Back to the topic at hand which centers on how to calculate interim account values for a contract holder when their contract assets are split between a separate account containing assets with daily pricing and the carrier’s general account with no divisible interest or earmarked asset allocated to the contract. I believe the conclusions to be drawn from the terminology created thus far are not helpful. I concur with several of the previous commenters that variable annuity Model 250 should govern, and not by amendments to the Model but rather with amendments to the products. This interim value debate is created by non-adherence to the time-tested traditional structure of variable annuities.

If ILVA’s must persist in their current form I would advocate for a simple prorata earnout of the buffer, floor, and cap without regard to Market Value Adjustment’s on hypothetical assets or the market price of the underlying hypothetical options. If a withdrawal is needed halfway

---

1 Interim Values Defined

As noted in PAG2, the terminology required to address ILVA features is currently lacking and these efforts to standardize and codify such terminology are admirable. The Proposed Actuarial Guideline 2 defines the Interim Value as follows:

“Interim Value” mean the Strategy Value at any time other than the start date and end date of an Index Term. (Index Term is not defined but I will assume it means the period described as the “Index Strategy Term”)

So, we must look to the Strategy Value – “Strategy Value” means the value, attributable to an Index Strategy, used in determining values including death benefit, withdrawal amount, annuitization amount or surrender values.

If the Interim Value we seek is equal to the Strategy Value on days other than the beginning and ending of an Index Strategy Term then these definitions give us nothing upon which to perform the math.

Later in PAG2, one of the three principles of the guideline states:

3. Interim Values defined in the contract provide equity to both the contract holder and the company where the Interim Values are consistent with the value of the Hypothetical Portfolio over the index term.

Here is the clue that the Interim Values are to be consistent with, presumably equal to, the value of a Hypothetical Portfolio. The Hypothetical Portfolio is also defined as:

“Hypothetical Portfolio” means a hypothetical portfolio composed of a Fixed Income Asset Proxy and a Derivative Asset Proxy.

Therefore, the Strategy Value at times other than the beginning or ending date of the Index Strategy Term is the current Hypothetical Portfolio Value which is the sum of the Derivative Asset Proxy Value, a hypothetical, and the Fixed Income Asset Proxy Value, a value also based on a hypothetical Fixed Income Asset. I understand this language is the result of comments on the previously proposed guideline expressing concerns that using a real asset could produce varying results. Transparency is not the long suit here.
through an index period, a client would expect to receive half the downside protection available, and half the cap purchased. Asking the consumer to be blind to daily values over many years, only to be priced to the market and current interest rates at the time of a needed withdrawal is not equitable.

Solution

I feel ILVA’s should be required to strictly adhere to the traditional form of a variable annuity. Such a structure would serve the investing public, create full and fair disclosure of all risks and holdings, and help standardize terms for a basis of competitive comparison, and solve the interim valuation debate. It would also allow for the addition of several other subaccounts to assist in navigating the markets. ILVA’s employ short-term alternative strategies as their sole funding option. This is leading to excessive allocations to the product as an accumulation vehicle in a strategy most professionals agree should not exceed 15% of an investor’s portfolio.

Include all premiums in the separate account (and relevant subaccounts), only allowing dollars to flow to the carrier’s general account according to the well-defined expenses and amounts detailed in the prospectus.

The Interim Value discussion is important but is largely irrelevant until the more glaring fatal flaws are addressed.

Respectfully,

Burt A. Snover, CLU, ChFC President

Re: Exposure 2 of the Proposed Actuarial Guideline ILVA, Nonforfeiture Requirements for
Index Linked Variable Annuity Products Supported by Non-Unitized Accounts

Dear Mr. Weber,

On behalf of the American Academy of Actuaries\(^1\) Index-Linked Variable Annuity Work Group
(the “work group”), I appreciate the opportunity to provide comments on the proposed actuarial
 guideline.

This is a complex topic with relationship to several product components such as filing
requirements, Interstate Insurance Compact standards, disclosures, illustrations, marketing, and
valuation that may need to be addressed separately. We offer the following conceptual comments
for your consideration:

1. We suggest additional clarification in the scope of the proposed actuarial guideline that
differentiates index-linked variable annuities (ILVAs) from variable annuities (VAs) and
fixed-index annuities (FIAs). We note that ILVAs generally have the following
characteristics:
   a. Index-based crediting;
   b. Risk of loss throughout the life of the contract;
   c. No absolute floor applied to the Interim Value for withdrawals, surrender values,
      death benefits, or annuitized values;
   d. Funding using a separate account, the general account, or both; and
   e. Non-unitized structures.

2. We suggest that the guideline be based on two principles:
   • Interim Values provide equity to both the contract owner and the life insurance
     company; and
   • Interim Values are consistent with the market value of a Hypothetical Portfolio over
     the index term.

\(^1\) The American Academy of Actuaries is a 19,500-member professional association whose mission is to serve the
public and the U.S. actuarial profession. For more than 50 years, the Academy has assisted public policymakers on
all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues. The
Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.
The other proposed principles in the draft relate to the derivative assets and their value. Thus, these principles are assumptions that need to be considered, but do not rise to the level of guiding principles for the guideline. Therefore, we suggest these other proposed principles be deleted.

3. A principal of consistency, in the generic sense, will allow each company to define consistency for its product. This may not be interpreted identically by each state regulator.

4. We suggest clarification on the demonstration of consistency. Is the intent to be symmetrical or to provide downside protection?

5. We suggest more clarification on the intended timing of the demonstration of consistency—in other words, is the demonstration to be performed solely on the basis of assumptions at issue? At the time of product filing? On a periodic basis? Etc.

We additionally propose the undermentioned specific language changes in the following sections:

Definitions:

We suggest adding “static” to the definition of “Derivative Asset Proxy” to help promote consistency in the application of the actuarial guideline:

“Derivative Asset Proxy” means a package of hypothetical static derivative assets designed to replicate credits provided by an Index Strategy at the end of an Index Term.

Text:

We suggest simplifying the description of Interim Value because Hypothetical Portfolio has previously been defined, defining the base to apply the hedge position, and combining the concepts of the two paragraphs into one:

Contracts in the scope of this guideline must provide Interim Values that are consistent with the value of the Hypothetical Portfolio over the index term, less a provision for the cost of unwinding the hedge positions not to exceed 10 bps of the Index Strategy Base.

Our work group appreciates the efforts of the Index-Linked Variable Annuity (A) Subgroup on this proposed actuarial guideline. If you have any questions or would like further dialogue on the above topics, please contact Amanda Barry-Moilanen, life policy analyst, at barrymoilanen@actuary.org.

Sincerely,

Beth Keith, MAAA, FSA
Chairperson, Index-Linked Variable Annuities Work Group

From: Ben Slutsker, Chair  
The VM-22 (A) Subgroup

To: Mike Boerner, Chair  
The Life Actuarial (A) Task Force

Subject: The Report of the VM-22 (A) Subgroup to the Life Actuarial (A) Task Force

The VM-22 (A) Subgroup has been meeting roughly every other week since the beginning of April. The focus of calls thus far have been addressing comments from multiple interested parties and regulators on the July 2021-exposed draft of VM-22 principles-based requirements.

The Subgroup’s process of reviewing feedback on the VM-22 exposure has been to divide up the comments into four tiers. The first tier contains the highest priority issues, and each subsequent tier is incrementally less substantive. Thus far, the Subgroup has worked through all tier 1 and tier 2 comments, and is in the midst of discussing tier 3 comments. Upon the resolution of remaining tier 3 comments, the VM-22 document will be re-exposed with modifications to reflect the agreed upon changes, as well as edits to address tier 4 comments. Among the items the Subgroup has addressed, notable ones include:

- **Aggregation** – Follow “Option 1” for payout and accumulation reserving category language (i.e., defining the payout reserving category consistent with the current scope of VM-22), which will then be used to restrict stochastic reserve aggregation between payout and accumulation annuities

- **Small Company Exemption** – Develop a small company exemption, akin to the Life PBR Exemption that exists for VM-20

- **Exclusion Test** – Allow SPIAs below a certain durational threshold to automatically pass the exclusion test, prohibit pension risk transfers from the certification method exclusion test, limit aggregation for contracts with significantly different risk profiles, and restrict future premiums from denominator of the ratio test

- **Mortality** – Permit only prescribed tables to be used for pension risk transfer and longevity reinsurance mortality upon limited or no experience (i.e., restrict company-selected third party tables from being used)

- **Longevity Reinsurance** – The Subgroup has exposed a proposal to treat longevity reinsurance as a third reserving category, along with language that would limit loading on recurring gross premiums from being reflected in the stochastic reserve

After the VM-22 language is re-exposed, the Subgroup will transition to addressing the development of the standard projection amount. The Subgroup has decided to recommend a standard projection...
amount to the Life Actuarial Task Force but has not decided on whether to recommend such as a disclosure-only item or as a minimum floor. There are currently two NAIC drafting groups: one led by Seong-min Eom (NJ) working on development of mortality assumptions and another led by Vincent Tsang (IL) working on policyholder behavior assumptions. Representatives from the SOA, Academy, and industry participate on these drafting group calls and the SOA Individual Annuity Experience Committee is assisting with assumption development. The goal will be to target a draft of the Standard Projection Amount to discuss during Subgroup calls in the Fall.

The Subgroup is also targeting a VM-22 field test to begin in Spring 2023, which will be led jointly by the Academy, ACLI, and NAIC. This timing may result in an effective date of 1/1/2025 (with a three year transition period for implementation), but the timeline will be revisited as progress in the Subgroup continues to develop.
Valuation Manual (VM)-22 (A) Subgroup  
Virtual Meeting  
July 19, 2022

The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met July 19, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Mike Yanacheak (IA); Nicole Boyd (KS); William Leung (MO); Bill Carmello and Amanda Fenwick (NY); Mike Boerner, Rachel Hemphill, and Yujie Huang (TX); and Craig Chupp (VA).

1. Reviewed the VM-22 Project Timeline

Mr. Slutsker reviewed the VM-22 project timeline (Attachment Nineteen-A). He said the target effective date is January 2025.

2. Discussed Tier Three Comments in the VM-22 Draft

Mr. Slutsker said the Subgroup will continue to review tier three comments on the proposed VM-22 framework (Attachment Nineteen-B). Ms. Hemphill agreed to defer discussion of the Texas Department of Insurance (TDI) comment on the appropriateness of risk-based capital (RBC) factors, as it is more related to RBC requirements than reserve requirements.

The TDI commented that the use of the term “VM-22 PBR requirements” needs to be clarified. Mr. Slutsker said that the confusion stems from adding the proposed principle-based reserving (PBR) requirements for non-variable annuities to the existing VM-22, Statutory Maximum Valuation Interest Rates for Income Annuities. He said the TDI comment questions whether the proposed PBR requirements should be a new chapter “VM-23.” Mr. Chupp suggested that a Subgroup name change may be necessary if the PBR requirements become “VM-23.” He said it may be easier to change the existing VM-22 to VM-23. Mr. Bayerle said that making the change may be awkward because it may cause a product that passes an exclusion test to jump between chapters. Ms. Lam asked if adding to VM-22 an appendix that specifically houses the rates might avoid the need for a new chapter. Mr. Bayerle asked if adding an appendix to the Valuation Manual that houses interest rates for other chapters, including VM-20, Requirements for Principle-Based Reserves for Life Products, might be the best solution. Mr. Slutsker said that the idea sounds viable, but more research is needed.

In response to an American Council of Life Insurers (ACLI) comment requesting more guidance on pre-reinsurance reserves in Section 3, Mr. Slutsker pointed to additional guidance provided in Section 5. Mr. Bayerle agreed to look at Section 5 to see if its guidance answers the ACLI concerns.

Mr. Slutsker agreed with the TDI comment that in Section 3.D.2, the term “scenario reserve” should be replaced with “deterministic reserve” (DR). Mr. Bayerle said that changing the term to DR addresses his concern about the use of the term “deterministic certification option.”

The Subgroup agreed to: 1) change the title of Section 3.E from “Exclusion Test” to “Stochastic Exclusion Test”; 2) delete the guidance note in Section 3.E.1; 3) add Section 3.H for consistency with VM-21, Requirements for Principle-Based Reserves for Variable Annuities; and 4) add a drafting note suggesting that the Life Actuarial (A) Task Force review the consistency of the language requiring periodic review of the prudent estimate assumption to ensure it is consistent across chapters and whether the word “periodically” should be replaced with “every three years.”
Mr. Slutsker said a comment suggested using stochastic mortality in the stochastic reserve calculation for longevity reinsurance. Sheldon Summers (Claire Thinking) said the language in Section 8.C.2 of VM-20 that when a prudent estimate does not appropriately capture the risk, the risk factor should be stochastically modeled to determine the impact. He said that language should be included in Section 4 of the proposed VM-22 framework.

Having no further business, the VM-22 (A) Subgroup adjourned.

© 2022 National Association of Insurance Commissioners
Section 1: Background

A. Purpose

Sections 1 through 13 of these requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2024. Section 14 of these requirements establish the maximum valuation rate for payout annuities for contracts issued on or after 1/1/2018. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts and certificates, the Commissioners Reserve Valuation Method (CRVM).

Guidance Note: CRVM requirements apply to some group pension contracts.

Guidance Note: Relationship to RBC Requirements

These requirements anticipate that the projections described herein are used for the determination of RBC for all of the contracts falling within the scope of these requirements. These requirements and the RBC requirements for the topics covered within Sections 4.A through 4.E are identical. However, while the projections described in these requirements are performed on a basis that ignores federal income tax, a company may elect to conduct the projections for calculating the RBC requirements by including projected federal income tax in the cash flows and reducing the discount interest rates used to reflect the effect of federal income tax as described in the RBC requirements. A company that has elected to calculate RBC requirements in this manner may not switch back to using a calculation that ignores the effect of federal income tax without approval from the domiciliary commissioner.

B. Principles

The projection methodology used to calculate the stochastic reserve $SR$ is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves.

Guidance Note: The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

**Principle 1:** The objective of the approach used to determine the stochastic reserve $SR$ is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

**Principle 2:** The calculation of the stochastic reserve $SR$ is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cash...
flow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions and reserving categories) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve $SR$ at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

**Guidance Note:** Examples where full aggregation between contracts may not be possible include experience rated group contracts and the operation of reinsurance treaties.

**Principle 3:** The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the stochastic reserve $SR$ at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve $SR$, the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

**Guidance Note:** The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle. More guidance and requirements for setting assumptions in general are provided in Section 12.

**Principle 4:** While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve $SR$ is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

**Principle 5:** Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve $SR$. Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve $SR$ without also reducing risk on scenarios similar to those used...
in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

C. Risks Reflected and Risks Not Reflected

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and
   b. Capable of materially affecting the reserve.

2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
      i. Credit risks (e.g., default or rating downgrades).
      ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).
      iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).
      iv. Performance of equities, real estate, and Schedule BA assets.
      v. Call risk on callable assets.
      vi. Separate account fund performance.

Drafting Note: Feedback welcome on whether to remove reference to separate accounts in VM-22. Whether references to separate accounts are retained or removed, consider making the treatment of such references consistent throughout VM-22.

   vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).
   viii. Currency risk.

b. Liability risks
   i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.
   ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.
iii. Utilization risk associated with guaranteed living benefits.
iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.
v. Annuization risks.
vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).
vii. Applicable expense risks, including fluctuation in maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks
i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.
ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).
iii. Risks associated with revenue-sharing income.

The risks not necessarily reflected in the calculation of reserves under these requirements include:

a. Those not associated with the policies or contracts being valued, or their supporting assets.
b. Determined to not be capable of materially affecting the reserve.

Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:

a. Asset risks
i. Liquidity risks associated with a sudden and significant levels of withdrawals and surrenders (“run on the bank.”)

b. Liability risks
i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.
ii. Catastrophic events (e.g., epidemics or terrorist events).
iii. Major breakthroughs in life extension technology that have not yet fundamentally altered recently observed mortality experience.
iv. Significant future reserve increases as an unfavorable scenario is realized.

c. General business risks
i. Deterioration of reputation.
ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.
iii. Poor management performance.
iv. The expense risks associated with fluctuating amounts of new business.
v. Risks associated with future economic viability of the company.
vi. Moral hazards.
vii. Fraud and theft.
viii. Operational.
ix. Litigation.

D. Specific Definitions for VM-22

Buffer Annuity
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

- **Deferred Income Annuity (DIA)**
  An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin one year [3 months] or later after (or from) the issue date if the contract holder survives to a predetermined future age.

- **Fixed Indexed Annuity (FIA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, subject to certain limits, typically with guaranteed principal.

- **Flexible Premium Deferred Annuity (FPDA)**
  An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

- **Funding Agreement**
  A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.
A guaranteed investment contract (GIC) is an insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

**Index Credit Hedge Margin**
A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

**Index Credit**
Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to contract policy values that is linked to an index or indices. Amounts credited to the contract policy resulting from a floor on an index account are included.

**Index Crediting Strategy**
The strategy defined in a contract to determine index credits for a contract. This refers to underlying index, index parameters, date, timing, performance triggers, and other elements of the crediting method.

**Index Parameter**
Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

**Longevity Reinsurance**
An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular,
contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

- **Market Value Adjustment (MVA) Annuity**
  An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

- **Modified Guaranteed Annuity (MGA)**
  A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values and death benefits that are based upon a market-value adjustment formula if held for shorter periods.

- **Multiple-Year Guaranteed Annuity (MYGA)**
  A type of fixed non-vari annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

- **Pension Risk Transfer (PRT) Annuity**
  An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

- **Registered Index-Linked Annuity (RILA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

- **Single Premium Immediate Annuity (SPIA)**
  An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within 13 months one year after (or from) the issuance date.

- **Single Premium Deferred Annuity (SPDA)**
  An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also

---

Commented [X87]: We recommend editing the definition as follows: “A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account.

Commented [VM228888R7]: Edits to address this comment will be reflected in next exposure

Commented [X99]: To clarify definition of MGA, recommend adding “death benefits”

Commented [VM229088R8]: Edits to address this comment will be reflected in next exposure

Commented [CD91]: To better change all instances of “fixed annuity” to “non-vari annuity” to be consistent with the terminology introduced in Section 1.4 (and to be aligned with the actual VM-22 chapter name): “Multiple-Year Guaranteed Annuity”

Commented [VM229288R9]: Edits to address this comment will be reflected in next exposure

Commented [CD93]: "fixed annuity" is not defined. Is it better to change all instances of “fixed annuity” to “non-vari annuity” to be consistent with the terminology introduced in Section 1.4 (and to be aligned with the actual VM-22 chapter name)? An alternative could be to add a definition for “fixed annuity”, with the definition of it being a "non-vari annuity"

Commented [VM229488R0]: Edits to address this comment will be reflected in next exposure

Commented [VM229688R1]: Edits to address this comment will be reflected in next exposure

Commented [CD95]: Recommend keeping this as “multiple-year”

Commented [VM229888R2]: Edits to address this comment will be reflected in next exposure

Commented [X97]: Is “typically” intended to be a requirement in the definition? That is, to qualify as PRT must the insurance company have the asset risk?

Commented [VM229888R3]: Academy will review this comment as part of revisiting the longevity reinsurance

Commented [X99]: Is it unclear to us why RILA is defined in VM-22 when it is being used to exclude the product

Commented [VM221008R9]: ACII already following up on a proposal to address the scope and definition of...
include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.

- **Stable Value Contract**
  A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

- **Structured Settlement Contract (SSC)**
  A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

- **Synthetic Guaranteed Investment Contract (Synthetic GIC)**
  Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the contract policyholder or plan trust.

- **Term Certain Payout Annuity**
  A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

- **Two-Tiered Annuity**
  A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.

The term “cash surrender value” means, for the purposes of these requirements, the amount available to the contract holder upon surrender of the contract. Generally, it is equal to the account value less any applicable surrender charges, where the surrender charge reflects the availability of any free partial surrender options. However, for contracts where all or a portion of the account value is paid up on surrender and is subject to a market value adjustment, the cash surrender value shall reflect the market value adjustment consistent with the required treatment of the underlying assets. That is, the cash surrender value shall reflect any market value adjustments where the underlying assets are reported at market value, but it shall not reflect any market value adjustments where the underlying assets are reported at book value.

The term “guaranteed minimum death benefit” (GMDB) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount, or (ii) exceeds the minimum amount and as increased by an amount that may be either specified by or computed from other policies' contract values; and
Section 2: Scope and Effective Date

A. Scope

Subject to the requirements of this Sections 1 to 13 of VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

Products in scope of VM-22 include non-variable annuities which consist of, but are not limited to, the following list:

- Account Value Based Annuities
  1. Deferred Annuities (SPDA & FPDA)
  2. Multi-Year Guarantee Annuities (MYGA)
  3. Fixed Indexed Annuities (FIA)
  4. Market Value Adjustments (MVA)
  5. Two-tiered Annuities
  6. Guarantees/Benefits/Riders on Non-Variable Annuity Contracts

- Payout Annuities
  1. Single Premium Immediate Annuities (SPIA)
  2. Deferred Income Annuities (DIA)
  3. Term Certain Payout Annuities
  4. Pension Risk Transfer Annuities (PRT)
  5. Structured Settlement Contracts (SSC)
  6. Longevity Reinsurance
Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities and RILAs)
2. GIICS
3. Synthetic GIICS
4. Stable Value Contracts
5. Funding Agreements

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E. of VM-22.

B. Effective Date & Transition

Effective Date

These requirements apply for valuation dates on or after January 1, 2024.

Transition

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the first three years following the effective date of VM-22 PBR. If a company during the three-year transition period elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve (SR) (following the requirements of Section 4), plus the additional standard projection amount (following the requirements of Section 6), plus the DR for those contracts satisfying the Deterministic Certification Option, less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

Guidance Note: Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves (SRs), per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined: The Additional Standard Projection Amount

D. The Stochastic Reserve

The stochastic reserve is determined by applying one of the two standard projection methods defined in Section 6. The same method must be used for all contracts within a group of contracts that are aggregated together to determine the reserve. The company shall elect which method they will use to determine the additional standard projection amount. The company may not change that election post-reinsurance ceded. The reserve may be determined in aggregate across various groups of contracts within each Reserving Category as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles. However, groups of contracts within different Reserving Categories may not change that election post-reinsurance ceded.

1. The SR shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.G here.

2. The stochastic reserve (SR) amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve (SR) following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts within each Reserving Category as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles. However, groups of contracts within different Reserving Categories may not change that election post-reinsurance ceded.

Attachment Nineteen-B
Life Actuarial (A) Task Force
8/8–9/22
not be aggregated together in determining the SR. For the purposes of VM-22, Reserving Categories are classified as the following:

a. The “Payout Annuity Reserving Category” includes the following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits provided by variable annuities:
   i. Immediate annuity contracts;
   ii. Deferred income annuity contracts;
   iii. Structured settlements in payout or deferred status;
   iv. Fixed income payment streams resulting from the exercise of settlement options or annuitizations of host contracts issued;
   v. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest);
   vi. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts, once the contract funds are exhausted;
   vii. Certificates, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders fixed income payment streams upon their retirement; and
   viii. Pension Risk Transfer Annuities; and
   ix. Longevity Reinsurance.

b. The “Accumulation Reserving Category” are all annuities within scope of VM-22 under Section II of the NAIC Valuation Manual that are not in the “Payout Reserving Category”.

Drafting Note: Additional feedback is welcome for whether to permit optionality for categorizing guaranteed living benefit contracts with depleted fund value as either in the payout or accumulation reserving category.

Commented [VM22177]: Include in deferred annuity benefits in payout reserving category or accumulation reserving category?

Commented [VM22178R177]: The Subgroup has elected to leave these contracts in the payout annuity reserving category, but is adding to a drafting note to welcome feedback.

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

To the extent that these limits on the aggregation result in more than one model segment, the stochastic reserves \( SR \) shall equal the sum of the stochastic reserves \( SR \) amounts computed for each model segment and \( DR \) amounts computed for each model segment for which the company elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test

1. To the extent that certain groups of contracts pass one or more of the defined stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A and VM-C, with the exception of contract following Section 3.E.

a. For dividend-paying contracts, a dividend liability shall be established following requirements in VM-A and VM-C, as described above, for the base contract.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018; AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on or after 2018; Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contracts may not group together contract types with significantly different risk profiles when performing the exclusion tests should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserves in Section 13 above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements using the method outlined in Section 4213, with the exception of contract following Section 3.E which are to be calculated on a separate basis.

G. Prudent Estimate Assumptions

1. With respect to the Stochastic Reserves \( SR \) in Section 3.DC, the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements in Section 12 of Model #820 and must periodically at least every 3 years review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary Company shall set a new, adequate, anticipated experience assumption for the factor.
3. To determine the prudent estimate assumptions, the stochastic reserve SR shall also follow the requirements in Sections 4 and general assumptions including Section 9 for asset assumptions, Section 10 for contract policy holder behavior assumptions, and Section 11 for mortality assumptions, and Section 12 for general guidance and expense assumptions.

H. Approximations, Simplifications, and Modeling Efficiency Techniques

A company may use simplifications, approximations, and modeling efficiency techniques to calculate the SR and/or the additional standard projection amount required by this section if the company can demonstrate that the use of such techniques does not understate the reserve by a material amount, and the expected value of the reserve calculated using simplifications, approximations, and modeling efficiency techniques is not less than the expected value of the reserve calculated that does not use them.

Guidance Note:

Examples of modeling efficiency techniques include, but are not limited to:

1. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters.

2. Generating a smaller liability or asset model to represent the full seriati model using grouping compression techniques or other similar simplifications.

There are multiple ways of providing the demonstration required by Section 3.H. The complexity of the demonstration depends upon the simplifications, approximations or modeling efficiency techniques used. Examples include, but are not limited to:

1. Rounding at a transactional level in a direction that is clearly and consistently conservative or is clearly and consistently unbiased with an obviously immaterial impact on the result (e.g., rounding to the nearest dollar) would satisfy 3.H without needing a demonstration. However, rounding to too few significant digits relative to the quantity being rounded, even in an unbiased way, may be material and in that event, the company may need to provide a demonstration that the rounding would not produce a material understatement of the reserve.

2. A brute force demonstration involves calculating the minimum reserve both with and without the simplification, approximation or modeling efficiency technique, and making a direct comparison between the resulting reserve. Regardless of the specific simplification, approximation or modeling efficiency technique used, brute force demonstrations always satisfy the requirements of Section 3.H.

3. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters and providing a detailed demonstration of why it did not understate the reserve by a material amount and the expected value of the reserve would not be less than the expected value of the reserve that would otherwise be calculated. This demonstration may be theoretical, statistical or mathematical argument establishing, to the satisfaction of the insurance commissioner, general bounds on the potential deviation in the reserve estimate rather than a brute force demonstration.

4. Justify the use of randomly sampling withdrawal ages for each contract instead of
following the exact prescribed WDCM method by demonstrating that the random sampling method is materially equivalent to the exact prescribed approach, and the simplification does not materially reduce the Additional Standard Projection Amount and the final reported reserve. In particular, the company should demonstrate that the statistical variability of the results based on the random sampling approach is immaterial by testing different random sets, e.g., if randomly selecting a withdrawal age for each contract, the probability distribution of the withdrawal age should be stable and not vary significantly when using different random number sets.

Commented [X219]: Specific example should be tailored based on the SPA developed.

Commented [X220]: Added consistent with VM-21 Section 3.16, which was added to the 2022 VM.

Commented [VM2221R220]: Edits to address this comment will be reflected in next exposure.
Section 4: Determination of Stochastic Reserve \( SR \)

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Sections 4 and 9.D. The company shall project cash flows including the following:

\text{a.} \quad \text{Revenues (gross premium received by the company, including premium received from the policyholder or policyholder contract holder, (including any due premiums as of the projected start date).}

\begin{footnotesize}
\textbf{Guidance Note:} If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset.
\end{footnotesize}

\text{b.} \quad \text{Other revenues, including contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).}

\text{c.} \quad \text{All material benefits projected to be paid to the policyholder (including, but not limited to, death claims, surrender benefits, and variable benefit—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.}

\begin{footnotesize}
\textbf{Guidance Note:} Amounts charged to account values on general account business are not revenue examples include riders, charges, and expense charges.
\end{footnotesize}

\text{d.} \quad \text{Non-Guaranteed Elements (NGE) cash flows as described in Section 10.4f.}

\text{e.} \quad \text{Insurance company expenses (including overhead and investment maintenance expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses); other acquisition expenses associated with business in force as of the valuation date.}

\text{f.} \quad \text{Cash flows associated with any reinsurance.}

\text{g.} \quad \text{Cash flows from hedging instruments as described in Section 4.A.A.4.}
Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.

**Guidance Note:** Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance).

**Guidance Note:** Section 4.A.1 requires market value adjustments (MVAs) on liability cash flows to be reflected because in a cash flow model, assets are assumed to be liquidated at market value to cover the cash outflow of the cash surrender; therefore, inclusion of the market value adjustment aligns the asset and liability cash flows. This may differ from the treatment of MVAs in the definition of cash surrender value (Section 1.D), which defines the statutory reserve floor for which the values must be aligned with the annual statement value of the assets.

### 2. Grouping of Index Crediting Strategies

Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

### 3. Model Cells

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.
4. Modeling of Hedges

a. For a company that does not have a future hedging program but directly supporting the contracts falling under the scope of VM-22 stochastic reserve SR requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

   a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

   b) No hedge positions—in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program but directly supporting the contracts falling under the scope of VM-22 stochastic reserve SR requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

   a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders’ contract holders.

   b) Existing hedging instruments that are currently held by the company for this purpose offsetting the indexed credits in support of the contracts falling under the scope of these requirements shall be included in the starting assets. Existing hedging instruments that are currently held by the company not for any other purpose offsetting the indexed credits should be modeled consistently with the requirements of Section 4.A.4.a.ii.

   c) An Index Credit Hedge Margin for these hedge instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible

Commented [X246]: Given that Section 9 covers hedging, we would suggest considering moving parts of Section 4.A.4 to that section.

Commented [X247]: VM-22 took out the CDHS requirement and replaced it with “future hedging program”. Future hedging should not materiality reduce reserves or TAR if it is not well documented. The hedging DG is currently working on this for VM-20/VM-21. We will work with VM-22 subgroup to edit VM-22 accordingly.

Commented [X248]: Suggest rewording “Future hedging program” to “hedging program with future transactions” to avoid ambiguity.

Commented [CD249]: The word “future” to describe the “hedging program” here is confusing. What about current hedging programs with expected future hedge purchases? Why not just say “hedging program”? I also wanted to note that removing the concept of CDHS creates inconsistency with both VM-20 and VM-21. Why not retain it?

Commented [CD250]: same comment as above, about the word “future” being confusing

Commented [CD251]: contract holders

Commented [VM22252R251]: Edits to address this comment will be reflected in next exposure

Commented [X253]: “Any other purpose” in the last sentence seems overly broad and should be narrowed

Commented [VM22254R253]: Edits to address this comment will be reflected in next exposure

Commented [X255]: Specify “for this purpose” as “for offsetting the indexed credits”, specify “for any other purposes” as “not for offsetting the indexed credits”

Commented [VM22256R255]: Edits to address this comment will be reflected in next exposure

Commented [X257]:

Commented [VM22258R257]: Subgroup agreed to revisit this discussion after field testing.

Commented [CD259]: clarify verbiage by saying “hedging instruments” or “derivative instruments”

Commented [VM22260R259]: Edits to address this comment will be reflected in next exposure
company experience and be no less than \([X\%]\) multiplicatively of the interest credited. In the absence of sufficient and credible company experience, a margin of \([Y\%]\) shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than \([Y\%]\). It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve \(SR\).

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future. Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve \(SR\) as the weighted average of two CTE values; first, a CTE70 ("best efforts") representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE70 ("adjusted") which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i., if the company has an indexed credit hedging program, the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.i.c., in both the “best efforts” run and the “adjusted” run.

d) The use of products not falling under the scope of Section 1 through 13 requirements (e.g., variable annuities) as a hedge shall not be recognized in the determination of accumulated deficiencies.

**Guidance Note:** Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other hedging positions.

**Commented [X261]:** It is not clear how the stress testing can be used to support the index credit hedge margin. It is a test of the modeled strategy not actual performance and does not reflect any model error. We suggest that both back testing and stress testing be required and elaborated further. Clearly specify method and metrics used for the back testing with focus on all available recent relevant history, not limited to 12 months. Recommend defined stress periods for stress testing, e.g., 2008 financial crisis, 2020 COVID impaired market conditions.

**Commented [X262R261]:** We will repeat the comment from our first letter: "Regarding hedge breakage expense assumptions, are both sources of error reflected here - error in the hedging itself, and error in the ability to accurately model it? Should we be separately considering the two limitations to make sure they are both clear: 1) the real-world hedging error and 2) the modeling error in reflecting the future hedging? Current error factor discussions seem muddled."

**Commented [X263]:** Again, need to coordinate with Hedging DG.

**Commented [X264]:** Margins are discussed in a different section, so recommend deleting.

**Commented [X265]:** Edits were made to provide context and clarification for the requirements.

**Commented [VM22266R265]:** Edits to address this comment will be reflected in next exposure.

**Commented [X267]:** Edits to address this comment will be reflected in next exposure.

**Commented [VM22268R267]:** Edits to address this comment will be reflected in next exposure.

**Commented [CD269]:** It might be helpful to keep the parenthetical statement, with “variable annuities” as the example.

**Commented [VM22270R269]:** Edits to address this comment will be reflected in next exposure.
fixed income assets supporting the contracts, and a margin is reflected rather than modeling using a CTE/70 adjusted run with no future hedge purchases. If a company has a more comprehensive hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or economic hedging), an appropriate and documented bifurcation method should be used in the application of sections 4.A.4.b.i and 4.A.4.b.ii above for the hedge modeling and justification. Such bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

Guidance Note: The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.

5. Revenue Sharing

If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each of the requirements set forth in VM-21 Sections 4.A.5.a through 4.A.5.c are met.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods. Obligations remain at the end of the projection periods. Company can choose to run a shorter projection period but not shorter than 20 years and include the present value of the terminal benefits and expenses in the accumulated deficiency calculation.

7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. For a given scenario, the scenario reserve shall be determined using one of two methods described below:

   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defeasance of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period.

Guidance Note: The greatest present value of accumulated deficiencies can be negative.
The scenario reserve for any given scenario shall not be less than the cash surrender value with market value adjustment in aggregate on the valuation date for the group of contracts modeled in the projection.

2. Discount Rates

In determining the scenario reserve, unless using the direct iteration method pursuant to Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

a. The additional invested asset portfolio for a scenario is a portfolio of general account assets as of the valuation date, outside of the starting asset portfolio, that is required in that projection scenario so that the projection would not have a positive accumulated deficiency at the end of any projection year. This portfolio may include only (i) General Account assets available to the company on the valuation date that do not constitute part of the starting asset portfolio; and (ii) cash assets.

Guidance Note:

Additional invested assets should be selected in a manner such that if the starting asset portfolio were revised to include the additional invested assets, the projection would not be expected to experience any positive accumulated deficiencies at the end of any projection year.

It is assumed that the accumulated deficiencies for this scenario projection are known.

b. To determine the NAER on additional invested assets for a given scenario:

i. Project the additional invested asset portfolio as of the valuation date to the end of the projection period,
   a) Investing any cash in the portfolio and reinvesting all investment proceeds using the company’s investment policy.
   b) Excluding any liability cash flows.
   c) Incorporating the appropriate returns, defaults and investment expenses for the given scenario.

ii. If the value of the projected additional invested asset portfolio does not equal or exceed the accumulated deficiencies at the end of each projection year for the scenario, increase the size of the initial additional invested asset portfolio as of the valuation date, and repeat the preceding step.

iii. Determine a vector of annual earned rates that replicates the growth in the additional invested asset portfolio from the valuation date to the end of the

Commented [X282]: For products with market value adjustment, needs to be floored at cash surrender value with MVA.

Commented [VM2283R282]: Academy will work on developing a “working reserve” concept for products without cash surrender value, though the issue may be minimized given that payout annuities cannot be aggregated with accumulation annuities.

Commented [X284]: For products with market value adjustment, needs to be floored at cash surrender value with MVA.

Commented [X285]: We believe that assets held in the separate account with performance not impacting policyholder benefits should be modeled consistent with how the business is managed.
projection period for the scenario. This vector will be the NAER for the given scenario.

iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.c, as a safe harbor.

Guidance Note: There are multiple ways to select the additional invested asset portfolio at the valuation date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

Treasury Department interest rate curves, as well as investment return paths for index funds, equities, and fixed income assets shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.

D. Projection of Assets

1. Starting Asset Amount

   a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:

      i. Any hedge instruments held in support of the contracts being valued; and

      ii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i).

   b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described...
above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets

For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

**Guidance Note:** Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets

a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:

i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;

ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the modeled company investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results

Commented [X288]: This change was adopted for VM-20; Commented [VM22289R288]: Edits to address this comment will be reflected in next exposure
in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the model aggregate reserve shall be the higher of that produced by the modeled company investment strategy and any non-prescribed asset spreads shall be adjusted as necessary so that the aggregate reserve is not lower than that which would be obtained from use of the fixed income reinvestment assets and have the same weighted average life (WAL) as the reinvestment assets in the modeled company investment strategy and are all public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 20% PBR credit rating 3 (Aa2/AA)

iii. 40% PBR credit rating 6 (A2/A)

iv. 40% PBR credit rating 9 (Baa/BBB)

c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.iii and Section 4.D.4.a.iv, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.

Guidance Note: This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:
i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.E, as noted in 4.a ii above.

b. Cash flows from general account-index funds and general account equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.H.

E. Projection of Annuitization Benefits

1. Assumed Annuitization Purchase Rates

a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such purchase rates shall reflect the payout rate specified in the contract.

b. For purposes of projecting future elective annuitization benefits (including annuitizations stemming from the election of a GMIB) and withdrawal amounts from GMWBs, the projected annuitization purchase rates shall be determined...
assuming that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuitzation Options
   a. For contracts projected to elect future annuitization options (including annuitizations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections may shall assume the contract will stay in force, the projected periodic payments are paid, and the associated maintenance expenses are incurred.

F. Frequency of Projection and Time Horizon
   1. Use of an annual cash-flow frequency ("timestep") is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

Care must be taken in simulating fee income and expenses when using an annual time step. For example, recognizing fee income at the end of each period after market movements, but prior to persistency decrements, would normally be an inappropriate assumption. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

Guidance Note: As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs
   When determining a stochastic reserve SR, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve, additional standard projection amount, the SR, DR, and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both a post-reinsurance ceded and a pre-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

Reflection of Reinsurance Cash Flows in the DR or SR

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve SR and DR shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

i. In this section, reinsurance includes retrocession, and assuming company includes retrocessionaire.

ii. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

**Guidance Note:** Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

iii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iv. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the stochastic aggregate reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum aggregate reserve by the absolute value of such reductions in surplus.
b. In order to determine the stochastic reserve (SR) and deterministic reserve (DR), on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve (SR) and deterministic reserve (DR) shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard cointurance treaty, the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection based on using starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable method.

Guidance Note: For standard pro rata insurance treaties (those that do not include experience refunds), where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld cointurance; modified cointurance; cointurance with a trust. To the extent these assets would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard cointurance treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, *Principle-Based Reserves for Life Products under the NAIC Valuation Manual*, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsured policies belong and reflect the terms of the reinsurance agreement.

d. The company shall assume that the counterparties to a reinsurance agreement are knowledgeable about the contingencies involved in the agreement and likely to exercise the terms of the agreement to their respective advantage, taking into account the context of the agreement in the entire economic relationship between the parties. In setting assumptions for the NGE in reinsurance cash flows, the company shall include, but not be limited to, the following:

i. The usual and customary practices associated with such agreements.

ii. Past practices by the parties concerning the changing of terms, in an economic environment similar to that projected.

iii. Any limits placed upon either party’s ability to exercise contractual options in the reinsurance agreement.

iv. The ability of the direct-writing company to modify the terms of its policies in response to changes in reinsurance terms.

v. Actions that might be taken by a party if the counterparty is in financial difficulty.

3. Reserve Determined Upon Passing the Exclusion Test
If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance-ceded and post-reinsurance-ceded reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance-ceded reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance-ceded reserves might not, or vice versa.

4. Additional Standard Projection Amount

Where reinsurance is ceded, the additional standard projection amount shall be calculated as described in Section 6 to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties. The additional standard projection amount shall also be calculated pre-reinsurance ceded using the methods described in Section 6 but ignoring the effects of the reinsurance ceded.
Section 6: Standard Projection Amount To Be Determined

Commented [VM22355]: NY Comment Letter: Current CARVM standards should be a minimum floor for VM-22 policies, and only the stochastic reserve should permit grouping whereas the minimum floor should be seriatim.

Commented [X356]: SPA Section placement here still makes sense, but SPA under development.

Commented [VM22357]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.

Commented [NJ359]: Once this is written, the language from 4.4.3.4 for longevity reinsurance could be added here as well, i.e. the standard projection would use net premiums based on the k factor approach, using the standard projection prescribed assumptions. Floor on std projection is at the contract level.
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation if the stochastic exclusion test (SET) is satisfied for each of the group of contracts. The company has the option to calculate or not calculate the SET.

   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then for each group of contracts that passes the SET, the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups of contracts. If the reserve methodology described in Section 4 is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.

   c. A company may not exclude a group of contracts from the stochastic reserve calculation if the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 for those groups of contracts is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.

   d. A company may elect to automatically exclude one or more groups of policies from the stochastic reserve calculation without passing the stochastic exclusion test (SET) if all of the following are met for all contracts in the group or groups:

      i. All of the contracts are either:
         - Single Premium Immediate Annuities,
         - Term Certain Payout Annuities, or
         - Structured Settlement Contracts;

      ii. None of the contracts are pension risk transfer annuities (PRT) or are covered under a longevity reinsurance agreement;

      iii. Future payout benefits are either level or stay within 5% of the initial payout benefit amount over time;

      iv. There is either no or an immaterial level of policyholder options permitted within the contracts; and

      v. The average (Macaulay duration) of the liabilities of the contracts as measured from the issue date (or premium determination date) is less than [X].

B. Requirement to Pass the Type of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

Commented [X360]: Need to modify exclusion testing section to reflect SPA.

Commented [NJ361]: Longevity reinsurance likely to be scoped out of the stochastic reserve unless the stochastic reserve includes consideration of stochastic mortality. If it stays as stochastic interest only, then it probably does make sense that it would meet the exclusion testing. For exclusion testing, the k factor approach should continue to apply, and it should not be combined with other blocks of business.

Commented [VM22363R362]: Inconsistent groups vs. group references.

Commented [VM22363R364]: Please Section 4 method of stochastic reserve for Section 3 aggregate reserve if not using the SET.

Commented [VM22367R366]: Edits to address this comment will be reflected in next exposure.

Commented [CD368]: Edits to address this comment will be reflected in next exposure.

Commented [VM22369R368]: Edits to address this comment will be reflected in next exposure.

Commented [CD370]: See earlier comment about the phrase "future hedge program" being confusing.

Commented [X371]: Is "associated with the contracts" the same as the earlier use of "supporting the contracts"? Should the same verbage be used here? If there is asset hedging for the assets supporting the contracts, it should be included. Need to define "solely supporting" index credits, and also have criteria on the effectiveness/error and documentation of any such hedging that is allowed for excluded business.
1. Stochastic Exclusion Ratio Test (SERT)—Annually within 12 months before the
test date the company demonstrates that the groups of contracts pass the SERT defined in Section 7.C.

2. Stochastic Exclusion Demonstration Test—In the first year and at least once every three
   calendar years thereafter, the company provides a demonstration in the PBR Actuarial
   Report as specified in Section 7.D.

3. SET Certification Method—For groups of contracts that do not have guaranteed living
   benefits, future hedging programs, or pension risk transfer business, in the first year and
   at least every third calendar year thereafter, the company provides a certification by a
   qualified actuary that the group of contracts is not subject to material interest rate risk, mortality
   and/or longevity risk, or asset return volatility risk.

Guidance Note: The qualified actuary should develop documentation to support the actuarial
   certification that presents his or her analysis clearly and in detail sufficient for another actuary to
   understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not
   subject to material interest rate risk, mortality and/or longevity risk, or asset return volatility risk.
   Examples of methods a qualified actuary could use to support the actuarial certification include,
   but are not limited to:

   a) A demonstration that, using requirements under VM-A and VM-C, the group of contracts' reserves
      calculated using requirements under VM-A and VM-C are at least as great as the assets required
      to support the group of contracts and that the company’s cash-flow testing model under each of
      the 441 scenarios identified in this section or alternatively each of the New York seven economic
      scenarios, under each of the three mortality assumption factors identified in Section 7.C.

   b) A demonstration that the group of contracts passed the SERT within 36 months prior to the
      valuation date and the company has not had a material change in its interest rate risk, mortality
      and/or longevity risk, or asset return volatility risk.

   c) A qualitative risk assessment of the group of contracts that concludes that the group of
      contracts does not have material interest rate risk, mortality and/or longevity risk, or asset
      return volatility risk. Such assessment would include an analysis of product guarantees, the
      company’s non-guaranteed elements (NGEs) policy, assets backing the group of contracts,
      the company’s longevity risk, and the company’s investment strategy.

C. Stochastic Exclusion Ratio Test

1. In order to exclude a group of contracts from the stochastic exclusion SR requirements
   under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of
   (b-a)/a is less than 1 the greater of [x]%, where x is the percentage change that
   would trigger the company’s materiality standard, where:

   [additional text and numbers]
There are 47 (=16x3-1) combined economic and mortality scenarios that should be compared for 100% as the adjustment factor for mortality, both of which could lead to an incorrect test result. The biggest difference from the adjusted scenario reserve for the baseline economic scenario and necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario, as described in Appendix 1.E of VM-20, will reflect future mortality improvement in line with anticipated experience assumptions with no margins, with the following differences:

- Using NAER and discount rates defined in Section 4 specific to each scenario.
- Shall reflect future mortality improvement in line with anticipated experience assumptions.
- Shall not reflect correlation between longevity and economic risks.

The scenario reserve defined in Section 4, but with the following differences:

- Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph 7.C.2.a.i below using Section 7.C.1.b of this section.
- Using the interest rates and equity return assumptions specific to each scenario.
- Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.
- Shall reflect future mortality improvement in line with anticipated experience assumptions.
- Shall not reflect correlation between longevity and economic risks.

In calculating the ratio in subsection (Section 7.C.1) above:

- The company shall calculate an adjusted scenario reserve for the group of contracts for each of the 16 economic scenarios using the three levels of mortality adjustment factors that is equal to either (i) or (ii) below:
  
  i. The scenario reserve defined in Section 4, but with the following differences:
    
    a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph 7.C.2.a.i below using Section 7.C.1.b of this section.
    
    b) Using the interest rates and equity return assumptions specific to each scenario.
    
    c) Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.
    
    d) Shall reflect future mortality improvement in line with anticipated experience assumptions.
    
    e) Shall not reflect correlation between longevity and economic risks.

  ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:
    
    a) Using the interest rates and equity return assumptions specific to each scenario.
b) Using the mortality scalars described in Paragraph Section 7.C.1.b of this section.

c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current available baseline economic scenario and the 15 other-economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.

e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to conduct the stochastic exclusion ratio test under only a pre-reinsurance-ceded single basis upon determining the either pre-reinsurance-ceded basis upon determining the prior post-reinsurance reserve- ceded aggregate reserve.

(3) If the ratio calculated in this section is less than \([x]\)% pre-non-proportional reinsurance, but is greater than \([x]\)% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation \(\text{SERT} = \frac{(b-a)}{a}\) defined in Section 7.C.1 above

a) The pre-non-proportional reinsurance results are “gross of non-proportional,” with a subscript “\(gn\),” so denoted \(\text{SERT}_{gn}\)

b) The post-non-proportional results are “net of non-proportional,” with subscript “\(nn\),” so denoted \(\text{SERT}_{nn}\)

ii. If a block of business being tested is subject to one or more non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurance but ignoring the non-proportional contract(s), and “net of non- proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.
iii. So, if $\text{SERT}_{\text{g}} \geq [\text{SR}]_{\text{g}}$ but $\text{SERT}_{\text{a}} > [\text{SR}]_{\text{a}}$, then compute the largest percent increase in reserve (LPIR) = $(\text{b} - \text{a})/\text{a}$, both “gross of non-proportional” and “net of non-proportional.”

$L\text{PIR}_{\text{g}} = \frac{(b - a)}{a}$

$L\text{PIR}_{\text{a}} = \frac{(b - a)}{a}$

Note that the scenario underlying $b_{\text{g}}$ could be different from the scenario underlying $b_{\text{a}}$.

If $\text{SERT}_{\text{g}} \times L\text{PIR}_{\text{g}} / L\text{PIR}_{\text{a}} < [\text{SR}]_{\text{g}}$, then the block of contracts passes the SERT.

b. Another more qualitative approach is to calculate the adjusted scenario reserves for once every three calendar years thereafter that complies with the following:

- The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section of Section 7.D.2.a or Section 7.D.2.b and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve requirements using the methodology in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

   a. The demonstration shall provide a reasonable assurance that if the stochastic reserve was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve requirements.

   b. If, as of the end of any calendar year, the company determines the appropriate statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.

   c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an...
E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve SR for a group of contracts using a single deterministic economic scenario, subject to the following conditions.

   a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies contracts and certificates. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recurring premium payments, and guaranteed living benefits.

   b. The company certifies that the group of policies contracts and certificates is not supported by a reinvestment strategy that contains future hedge purchases.

   c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing the scenario reserve volatility across various scenarios. The company must pass the SERT when considering only the 16 economic scenarios paired with the 100% mortality scenario.
d. The company must disclose a description of contracts and associated features in the certification.

**Drafting Note:** Consider revising Paragraph E.1.c to possibly either require i) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario; or ii) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve SR for the group of contracts under the Deterministic Certification Option is determined as follows:

   a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).

   b. The stochastic reserve SR equals the scenario reserve following the requirements for Section 4.

**Guidance Note:** The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.

**Commented [X483]:** It may not be appropriate to use scenario 12 to calculate the scenario reserve for SPIA. See this article https://www.soa.org/sections/financial-reporting/financial-reporting-newsletter/2021/july/fr-2021-07-su/

“In an increasing interest rate environment for business where policyholder behavior is sensitive to prevailing interest rates, life insurers may face an increase in disintermediation risk (i.e., the risk of having to sell assets, potentially at a loss, to fund policyholder surrender benefits) For example, rising interest rates, particularly sudden jumps (e.g., New York 7 pop-up scenario with an immediate interest rate increase of 3 percent), may lead to higher actual and projected policyholder surrenders as policyholders seek out higher yielding investment opportunities. These increasing cash demands may require fixed income assets to be sold at depressed prices, and resultant projected losses (or lower gains) may result in reserve insufficiencies, necessitating the need for AAT reserves.”

**Commented [X486]:** Recommend deleting guidance note, as it doesn't provide full or clear scope of what may be excluded, so could be misread to either guarantee option for certain products or exclude the option for other products.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Non-Index Credit Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company, or (a) only hedges index credits, if the company, or (b) clearly separates index credit hedging from other hedging, then only the section only pertains to the other hedging if the index hedging followed. In those situations, the modeling of hedges supporting index credits can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.A.b.i.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be the actual practice of the company for a period of time not less than 6 months, including the hedging strategy, used to implement the investment policy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserves, otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserveSR otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserveSR needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserveSR attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock-tested.

Guidance Note: No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

C. Calculation of Stochastic ReserveSR (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no future hedging purchases except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.1.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserveSR is given by:

\[ \text{Stochastic reserveSR} = \text{CTE70 (best efforts)} + E \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}] \]
The company shall specify a value for $E$ (the “error factor”) in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of $E$. The value of $E$ may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, $E$ must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

The company shall conduct a formal back-test, based on an analysis of at least the most recent available relevant period of data (but no less than 12 months), to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for $E$.

Such a back-test shall involve one of the following analyses:

a. For companies that model hedge cash flows directly (“explicit method”), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses – both realized and unrealized – observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g., reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

To support the choice of a low value of $E$, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of $E$ by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an “implicit method” or “cost of reinsurance method”), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

i. Determine the hedge asset gains and losses—both realized and unrealized—incurred over the month attributable to equity, interest rate, and implied volatility movements.

ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risk hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).
iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.

iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with less than 6 months of history, E should be at least 1.0.50. However, E may be lower than 1.0.50 if at least 6 months of reliable experience is available and/or if the change in strategy is a minor refinement rather than a material change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).
8. The company shall set the value of E reflecting the extent to which the future hedging program is clearly defined. To support a value of E below 1.0, there should be very robust documentation outlining the future hedging program. To the extent that documentation outlining the future hedging program is incomplete, the value of E shall be increased. Any increases required to the value of E to reflect that documentation is not available to support that the future hedging program is clearly defined shall be in addition to increases to the value of E to reflect a lack of historical experience or to reflect the back-testing results.

E. Additional Considerations for CTE70 (Best efforts)

If the company is following a CDHS, the fair value of the portfolio of contracts falling within the scope of these requirements shall be computed and compared to the CTE70 (best efforts) and CTE70 (adjusted). If the CTE70 (best efforts) is below both the fair value and CTE70 (adjusted), the company should be prepared to explain why that result is reasonable.

For the purposes of this analysis, the SR and fair value calculations shall be done without requiring the scenario reserve for any given scenario to be equal to or in excess of the cash surrender value in aggregate for the group of contracts modeled in the projection.

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for purposes of reducing the stochastic reserve SR, the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions.
on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or adverse estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited to, a hedging strategy where material hedging assets will be obtained when the fixed indexed annuity and other in-scope products account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets. There may be scenarios that are particularly costly to discontinuous hedging strategies, especially where those result in large discontinuous changes in sensitivities (Greeks) associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve SR, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve SR otherwise calculated.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent
Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the reserves level. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B and Section 12.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may or may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more material behavior assumptions if relevant to the risks in the product, and thus the approach will not underestimate the reserve.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the company shall perform sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Account transfers.
- Future deposits.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently (but no less than every 3 years) when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
   b. Surrenders.
   c. Partial withdrawals (systematic and elective).
   d. Account transfers (switching/exchanges).
   e. Resets/ratchets of the guaranteed amounts (automatic and elective).
   f. Future deposits.
   g. Income start date for the benefit utilization.
   h. Commutation of benefit (from periodic payment to lump sum or vice versa).

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions. For example:
   a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing) or if the contract provisions incentivize the contract holders to transfer between accounts.
   b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).
   c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

Guidance Note: For some non-elective benefits (nursing home benefits for example), unless relevant company experience exists to the contrary, the use of incidence rates greater than zero after the surrender charge has ended, or the cash value was depleted might be inappropriate may not be prudent since it would reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.
4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):
   a. Gender.
   b. Attained age.
   c. Issue age.
   d. Contract duration.
   e. Time to maturity.
   f. Tax status.
   g. Account value.
   h. Interest credited (current and guaranteed).
   i. Available indices.
   j. Guaranteed benefit amounts.
   k. Surrender charges, transaction fees or other contract charges.
   l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve SR. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100% efficiency, nor assume that all contract holders will always act irrationally. This text seems to directly contradict Section II. Reserve Requirements 6.H.2 which states: "When advantageous, policyholders will commence living benefit payouts if not started yet.

Commented [X553]: This also applies to VM-21, as there are fixed accounts. Is there any reason not to be consistent?

Commented [VM2SS54R553]: Only to focus on VM-22 for now

Commented [X555]: This is not a synonym (perhaps transaction fees is a subset of transaction fees) - why would transaction fees apply for VM-21, but only transfer fees for VM-22?

Commented [VM2SS56R555]: Edits to address this comment will be reflected in next exposure

Commented [X557]: This section states that "contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally." This text seems to directly contradict Section II. Reserve Requirements 6.H.2 which states: "When advantageous, policyholders will commence living benefit payouts if not started yet." We suggest revising 6.H.2 to align with the text of 10.D.8.
efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., the non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holders stochastically modeled.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable appropriate to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practical allowance for appropriate simplifications, approximations and modeling efficiency techniques, the use of dynamic models is encouraged, but not mandatory. Static assumptions: Risk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers), may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of "valuation" scenarios would typically display one or more of the following attributes:

   a. Declining, increasing and/or volatile index values, where applicable.

   b. Price gaps and/or liquidity constraints.

   c. Rapidly changing interest rates or persistently low interest rates.

   d. Volatile credit spreads.

4. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions.
Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:
   a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.
   b. Complies with the contract holder behavior requirements stated in Section 10.A to Section 10.G above in this section.

2. If the company models policy loans explicitly, the company shall:
   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.
   b. Assign loan balances either to exactly match each policy’s contract’s utilization or to reflect average utilization over a model segment or sub-segments if the results are materially similar.
   c. Model policy loan interest in a manner consistent with policy contract provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
I. Non-Guaranteed Elements

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policyholder costs or values and are not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to non-variable annuities include but are not limited to the following: fixed rates on fixed accounts, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollup rates, rollup period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.I.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of NGE that:
   a. Is not based on some aspect of the policy’s or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

   However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude...
from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.

a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve, $SR$.

b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve, $SR$ should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the valuation reserve. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.)

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from similar industries or geographies that may be used to sub-divide inforce blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to...
4. Margin for Data Uncertainty

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) mortality (longevity) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a mortality (longevity) plus (minus) segment to a longevity (mortality) minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2 for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

Guidance Note: Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.
i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:

\[ q_{x}^{20XX+n} = q_{x}^{20XX}(1 - G_{x})^{n} \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage \( (F_{x}) \) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual deferred annuities and deferred annuity contracts with guaranteed living benefits

\[ q_{x}^{2012+n} = q_{x}^{2012}(1 - G_{x})^{n} \cdot F_{x} \]

b. [1983 Table “a”] for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_{x}^{1994+n} = q_{x}^{1994}(1 - AA_{x})^{n} \]

</table>
iii. For a business segment with non-U.S. insureds, when little or no experience or information is available on a business segment, an established industry or national mortality table and mortality improvement scale may be used, with approval from the domiciliary commissioner.

4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

a. Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

b. Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by...
contract duration for an appropriate select period. As an alternative, if the company
determines that mortality is affected by selection, the company could apply
margins to the expected mortality in such a way that the actual mortality modeled
does not depend on contract duration.

c. Modification and Relevance of Data

Even for a large company, the quantity of life exposures and deaths are such that
a significant amount of smoothing may be required to determine expected
mortality curves from mortality experience. Expected mortality curves, when
applied to the recent historic exposures (e.g., three to seven years), should not
result in an estimate of aggregate number of deaths less (greater) than the actual
number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying
data), older data may no longer be relevant. The "age" of the experience data used
to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors
that include, but are not limited to, trends in mortality experience, trends in
exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative
to mortality by amounts, changes in the mix of business and product features that
could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the
credibility of the experience used to determine the curves in order to arrive at prudent
estimate mortality. The adjustment for credibility shall result in blending the expected
mortality curves including margins for uncertainty with the mortality assumptions described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

Guidance Note: For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the industry mortality assumption described in Section 11.B.3 used in the blending.

2. Adjustment of Statutory Valuation Industry Mortality for Improvement

For purposes of the adjustment for credibility, the industry mortality table for a plus segment may be and the industry mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective industry mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.
b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.

f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve $SR$. If such an adjustment would reduce the stochastic reserve $SR$, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Other Guidance and Requirements for Assumptions

A. Overview

This section provides guidance and requirements in general for setting prudent estimate assumptions when determining either the SR or DR. It also provides specific guidance and requirements for expense assumptions.

B. General Assumption Requirements

1. The company shall use prudent estimate assumptions for risk factors that are not stochastically modeled by applying margins to the anticipated experience assumptions if such risk factors have been categorized as material risks by following Section 1.B Principle 3 and requirements in Section 12.C.

2. The company shall establish the prudent estimate assumptions for risk factors in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

3. The company shall model the following risk factors stochastically unless the company elects to stochastic model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.

   a. Interest rate movements (e.g., Treasury interest rate curves).
   b. Equity performance (e.g., Standard & Poor’s 500 index [S&P 500] returns and returns of other equity investments).

4. If the company elects to stochastically model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.

   Guidance Note: It is expected that companies will not stochastically model risk factors other than the economic scenarios, such as contract holder behavior or mortality, until VM-22 has more specific guidance and requirements available. Companies shall discuss with domiciliary regulators if they wish to stochastically model other risk factors.

5. The company shall use its own experience, if relevant and credible, to establish an anticipated experience assumption for any risk factor. To the extent that company experience is not available or credible, the company may use industry experience or other data to establish the anticipated experience assumption, making modifications as needed to reflect the circumstances of the company.

   a. For risk factors (such as mortality) to which statistical credibility theory may be appropriately applied, the company shall establish anticipated experience assumptions for the risk factor by combining relevant company experience with industry experience data, tables or other applicable data in a manner that is consistent with credibility theory and accepted actuarial practice.
b. For risk factors (such as utilization of guaranteed living benefits) that do not lend themselves to the use of statistical credibility theory, and for risk factors (such as some of the lapse assumptions) to which statistical credibility theory can be appropriately applied but cannot currently be applied due to lack of industry data, the company shall establish anticipated experience assumptions in a manner that is consistent with accepted actuarial practice and that reflects any available relevant company experience, any available relevant industry experience, or any other experience data that are available and relevant. Such techniques include:

i. Adopting standard assumptions published by professional, industry or regulatory organizations to the extent they reflect any available relevant company experience or reasonable expectations.

ii. Applying factors to relevant industry experience tables or other relevant data to reflect any available relevant company experience and differences in expected experience from that underlying the base tables or data due to differences between the risk characteristics of the company experience and the risk characteristics of the experience underlying the base tables or data.

iii. Blending any available relevant company experience with any available relevant industry experience and/or other applicable data using weightings established in a manner that is consistent with accepted actuarial practice and that reflects the risk characteristics of the underlying contracts and/or company practices.

c. For risk factors that have limited or no experience or other applicable data to draw upon, the assumptions shall be established using sound actuarial judgment and the most relevant data available, if such data exists.

d. For any assumption that is set in accordance with the requirements of Section 12.B.5.c, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing and disclose the analysis performed to ensure that the assumption is set at the conservative end of the plausible range.

e. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

6. The company shall sensitivity test risk factors that are not stochastically modeled and examine the impact on the stochastic reserve. The company shall update the sensitivity tests periodically as appropriate. The company may update the tests less frequently, but no less than every 3 years, when the tests show less sensitivity of the stochastic reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company...
may perform sensitivity testing:

a. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
b. Using data from prior periods.

Guidance Note: Sensitivity testing every risk factor on an annual basis is not required. For some risk factors, it may be reasonable, in lieu of sensitivity testing, to employ statistical measures for margins, such as adding one or more standard deviations to the anticipated experience assumption.

7. The company shall vary the prudent estimate assumptions from scenario to scenario within the stochastic reserve calculation in an appropriate manner to reflect the scenario-dependent risks.

C. Assumption Margins

The company shall include margins to provide for adverse deviations and estimation error in the prudent estimate assumption for each risk factor that is not stochastically modeled or prescribed, subject to the following:

1. The level of margin applied to the anticipated experience assumptions may be determined in aggregate or independently as discussed in Section 1.B Principle 3. It is not permissible to set a margin less toward the conservative end of the spectrum to recognize, in whole or in part, implicit or prescribed margins that are present, or are believed to be present, in other risk factors.

Risks that are stochastically modeled (e.g., interest rates, equity returns) or have prescribed margins or guardrails (e.g., assets, revenue sharing) shall be considered material risks. Other risks generally considered to be material include, but are not limited to, mortality, contract holder behavior, maintenance and overhead expenses, inflation and implied volatility. In some cases, the list of material risks may also include acquisition expenses, partial withdrawals, policy loans, annuitizations, account transfers and deposits, and/or option elections that contain an element of anti-selection.

2. The greater the uncertainty in the anticipated experience assumption, the larger the required margin, with the margin added or subtracted as needed to produce a larger Sr or DR than would otherwise result. For example, the company shall use a larger margin when:

a. The experience data have less relevance or lower credibility.
b. The experience data are of lower quality, such as incomplete, internally inconsistent or not current.
c. There is doubt about the reliability of the anticipated experience assumption, such as, but not limited to, recent changes in circumstances or changes in company policies.
d. There are constraints in the modeling that limit an effective reflection of the risk factor.
3. In complying with the sensitivity testing requirements in Section 12.B.6 above, greater analysis and more detailed justification are needed to determine the level of uncertainty when establishing margins for risk factors that produce greater sensitivity on the stochastic reserve.

4. A margin is permitted but not required for assumptions that do not represent material risks.

5. A margin should reflect the magnitude of fluctuations in historical experience of the company for the risk factor, as appropriate.

6. The company shall apply the method used to determine the margin consistently on each valuation date but is permitted to change the method from the prior year if the rationale for the change and the impact on the stochastic reserve is disclosed.

D. Expense Assumptions

1. General Prudent Estimate Expense Assumption Requirements

In determining prudent estimate expense assumptions, the company:

a. May spread certain information technology development costs and other capital expenditures over a reasonable number of years in accordance with accepted statutory accounting principles as defined in the Statements of Statutory Accounting Principles.

Guidance Note: Care should be taken with regard to the potential interaction with the inflation assumption below.

b. Shall assume that the company is a going concern.

c. Shall choose an appropriate expense basis that properly aligns the actual expense to the assumption. If values are not significant, they may be aggregated into a different base assumption.

Guidance Note: For example, death benefit expenses should be modeled with an expense assumption that is per death incurred.

d. Shall reflect the impact of inflation.

e. Shall not assume future expense improvements.

f. Shall not include assumptions for federal income taxes (and expenses paid to provide fraternal benefits in lieu of federal income taxes) and foreign income taxes.

Guidance Note: Expense assumptions should reflect the direct costs associated with the block of contracts being modeled, as well as indirect costs and overhead costs that have been allocated to the modeled contracts.

g. Shall use assumptions that are consistent with other related assumptions.

h. Shall use fully allocated expenses.

Guidance Note: For example, death benefit expenses should be modeled with an expense assumption that is per death incurred.

i. Shall allocate expenses using an allocation method that is consistent across
company lines of business. Such allocation must be determined in a manner that is within the range of actuarial practice and methodology and consistent with applicable ASOPs. Allocations may not be done for the purpose of decreasing the stochastic reserve.

j. Shall reflect expense efficiencies that are derived and realized from the combination of blocks of business due to a business acquisition or merger in the expense assumption only when any future costs associated with achieving the efficiencies are also recognized.

Guidance Note: For example, the combining of two similar blocks of business on the same administrative system may yield some expense savings on a per unit basis, but any future cost of the system conversion should also be considered in the final assumption. If all costs for the conversion are in the past, then there would be no future expenses to reflect in the valuation.

k. Shall reflect the direct costs associated with the contracts being modeled, as well as an appropriate portion of indirect costs and overhead (i.e., expense assumptions representing fully allocated expenses should be used), including expenses categorized in the annual statement as “taxes, licenses and fees” (Exhibit 3 of the annual statement) in the expense assumption.

l. Shall include acquisition expenses associated with business in force as of the valuation date and significant non-recurring expenses expected to be incurred after the valuation date in the expense assumption.

m. For contracts sold under a new policy form or due to entry into a new product line, the company shall use expense factors that are consistent with the expense factors used to determine anticipated experience assumptions for contracts from an existing block of mature contracts taking into account:

i. Any differences in the expected long-term expense levels between the block of new contacts and the block of mature contracts.

ii. That all expenses must be fully allocated as required under Section 12.D.1.h above.

2. Margins for Prudent Estimate Expense Assumptions

The company shall determine margins for expense assumptions following Section 12.C.
Section 13: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

### Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The allocation shall be made separately for DR and SR. The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td>140</td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td></td>
<td>22</td>
</tr>
</tbody>
</table>

### Table 12.1: Sample Allocation of Aggregate Reserve

[Commented [X655]: This method only makes sense if done separately for the DR and SR.]
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

### Option 2: Actuarial Present Value Approach

B. The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve \( SR \) defined in Section 3.D.

   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows, as well as any cash flows that are scenario dependent.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.

   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve \( SR \) defined in Section 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

| Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value | Li = (A)/∑A*[Aggregate Reserve - ∑Cj] |
|---|---|---|---|
| | 9.09 | 10.91 | 0.00 | 20 |

| Contract-level reserve Ci+ Li | 37.09 | 50.91 | 52.00 | 140.00 |

Commented [X656]: This method depends on the NAER, so would not work for companies that use direct iteration.

Commented [X657]: This could give an unstable allocation if there is an even mix of products with different risk profiles, so that the tail is populated with some scenarios where Product A does poorly and some where Product B does poorly. The single scenario will only reflect the riskiness of one of the products.

Commented [X658]: Not just the NAER, but the cashflows are also scenario dependent.

Commented [VM22659R658]: Edits to address this comment will be reflected in next exposure.

Commented [CD660]: Section 3.D.

Commented [VM22661R660]: Edits to address this comment will be reflected in next exposure.

*Cash Surrender Value  
**Guaranteed Lifetime Withdrawal Benefit

**Guidance Note:** The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 1314: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section and all contracts not passing the SET covered by Sections 1 through 13 of VM-22, are covered Section 14 of VM-22:

   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

   **Guidance Note:** For Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f and Section 1314.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:

   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f, Section 1314.A.2.g or Section 1314.A.2.h, the...
company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 4.14 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, *Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B)* (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in *Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C)* (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 4.14.B.1.c above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   **Guidance Note:** If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.
3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.

4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her age last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 1314 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*
   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets

   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.

   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

   **Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only**
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5 Years</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>90+</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>80–89</td>
<td>B</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>70–79</td>
<td>C</td>
<td>C</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>&lt; 70</td>
<td>D</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

2. Premium Determination Dates
   a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d and A.2.e</td>
<td>Fixed payout annuities resulting from settlement options or annuitizations from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
<tr>
<td>A.2.g</td>
<td>Fixed income payment streams from CDAs, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
b. Immaterial Change in Consideration

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

3. Statutory Maximum Valuation Interest Rate

a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 1314.C.1) and its Premium Determination Date (Section 1314.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

d. Quarterly Valuation Rate:

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ I_q = R + S - D - E \]

Where:

a. R is the reference rate for that Valuation Rate Bucket (defined in Section 1314.C.4);

b. S is the spread rate for that Valuation Rate Bucket (defined in Section 1314.C.5);

c. D is the default cost rate for that Valuation Rate Bucket (defined in Section 1314.C.6);
and

d. E is the spread deduction defined as 0.25%.

e. Daily Valuation Rate:

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[ I_d = I_q + C_{d-1} - C_q \]

Where:

a. \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b. \( C_{d-1} \) is the daily corporate rate (defined in Section 1314.C.7) for the business day immediately preceding the premium determination date; and

c. \( C_q \) is the average daily corporate rate (defined in Section 1314.C.8) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate \( (I_d) \) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4. Reference Rate

Reference rates are updated quarterly as described below:

a. The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b. Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c. The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

5. Spread

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a. Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.I) effective for the calendar year in which the premium determination date falls.

6. Default costs for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAMLC1A0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAMLC2A0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAMLC3A0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAMLC4A0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAMLC7A0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAMLC8A0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 1314.C.7.a].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating \( i_q \) in Section 1314.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:

i. Bucket A:
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   b) Five-year certain only.

ii. Bucket B:
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   b) 10-year certain only.

iii. Bucket C:
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   c) 15-year certain only.

iv. Bucket D:
   a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
   b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for...
individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

   a) Column 1 of Table 4 is identical to column 1 of Table 1.
   b) Column 2 of Table 4 is 50% of column 2 of Table 1.
   c) Column 3 of Table 4 is identical to column 2 of Table 4.
   d) Column 4 of Table 4 is 50% of column 3 of Table 1.
   e) Column 5 of Table 4 is identical to column 4 of Table 4.
   f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 3.14.A.2.i), the following apply:

a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

Guidance Note: Under some group annuity contracts, certificates may be purchased on different
In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

Guidance Note: The statutory maximum valuation interest rate will not change when the form of payout is elected.
Valuation Manual Section II| Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for non-variable annuity contracts issued prior to 1/1/2024 are those requirements as found in Sections 1 through 13 of VM-22.

D. Minimum reserve requirements for non-variable annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 13 of VM-22.

The requirements in this section are still considered a part of PBR requirements and therefore are applicable to VM-G.

The below principles may serve as key considerations for assessing whether VM-21 or VM-22 requirements apply.

D. Minimum reserve requirements apply.

E. Indexed or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for application of VM-22 requirements and are issued on 1/1/2024 and later are those requirements as found in Sections 1 through 13 of VM-22:

1. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.

2.b. Credits a rate of interest under the contract prior to the application of any market value adjustments that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

Minimum reserve requirements.
Index-linked or modified guaranteed annuity contracts or riders that do not satisfy either of the two conditions listed above criteria in Paragraph Section 2.E.1.i and Section 2.E.2 above and E.1.i may be a key consideration for application of VM-21 are issued on 1/1/2024 and later are those requirements as found in VM-21.
Subsection 6: Riders and Supplemental Benefits

**Guidance Note:** Policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts, not subject to Paragraph C above, including but not limited to, Guaranteed Minimum Accumulation Benefits, Guaranteed Minimum Death Benefits, Guaranteed Minimum Income Benefits, Guaranteed Minimum Withdrawal Benefits, Guaranteed Lifetime Income Benefits, Guaranteed Lifetime Withdrawal Benefits, Guaranteed Payout Annuity Floors, Waiver of Surrender Charges, Return of Premium, Systematic Withdrawal Benefits under Required Minimum Distributions, and all similar guaranteed benefits shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.
2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.
3. After issuance, the base policy or contract value or benefits are determined by referencing the rider or supplemental benefit features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

E. If a term life insurance rider on the named insured(s) on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is
separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.

For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve (for VM-20 and VM-22) or TAR (for VM-21) if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves (for VM-20 and VM-22) or reserves and TAR (for VM-21) using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.
VM-01: Definitions for Terms in Requirements

- The term “Guaranteed Minimum Accumulation Benefit” (GMAB) means a guaranteed benefit providing, or resulting in the provision, that an amount payable on the contractually determined maturity date of the benefit will be increased and/or will be at least a minimum amount. Only such guarantees having the potential to produce a contractual total amount payable on benefit maturity that exceeds the account value, or in the case of an annuity providing income payments, an amount payable on benefit maturity other than continuation of any guaranteed income payments, are included in this definition.

- The term “guaranteed minimum death benefit” (GMDB) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount; or (ii) exceeds the minimum amount and is:
  - Increased by an amount that may be either specified by or computed from other policy or contract values; and
  - Contains either
    - The potential to produce a contractual total amount payable on such death that exceeds the account value, or
    - In the case of an annuity providing income payments, guarantees payment upon such death of an amount payable on death in addition to the continuation of any guaranteed income payments.

- The term “guaranteed minimum income benefit” (GMIB) means an option under which the contractholder has the right to apply a specified minimum amount that could be greater than the amount that would otherwise be available in the absence of such benefit to provide periodic income using a specified purchase basis.

Commented [X692]: We believe a Fixed Annuity PBR Exemption should be incorporated into draft in a manner consistent with the Life PBR Exemption.

Commented [VM22693R692]: The Subgroup voted in favor of a VM-22 PBR Exemption. The ACLI will follow up with proposed criteria for determining the exemption.

The term Buffer Annuity is not interchangeable to Registered Index-Linked Annuity (RILA) since Buffer Annuity is a subset of RILA. RILA can have different downside protections such as "Buffer" or "Floor". Recommend deleting Buffer Annuity or add descriptions for Buffer Annuity as a subtype in the RILA definition.

Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

The definition of FIA describes the account value as typically with guaranteed principal. Since FIA always has the guaranteed principal, recommend deleting the wording “typically”.

Is “typically” intended to be a requirement in the definition? That is, to qualify as PRT must the insurance company have the asset risk? Consistent with the comment on Longevity Reinsurance, it would be helpful to clarify where a longevity swap contract falls within these definitions. Notably, index-based longevity swaps should be out of scope as they do not meet definition of “annuity contract” in SSAP 50. It should also be made explicit that PRT contracts can include lump sum benefits, death benefits and cash balance benefits as well.

Academy will review this comment as part of revisiting the longevity reinsurance definition.

It is unclear to us why RILA is defined in VM-22 when it is being used to exclude the product from VM-22 requirements.

ACLI already following up on a proposal to address the scope and definitions, which will address this issue.

Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

The wording “after (or from)” the issue date used in the DIA and SPIA definitions is confusing. Recommend keeping it simple as “from” the issue date.

The VM-22 Subgroup voted to adopted “Option 1” for Reserving Categories.
See Equitable comment letter: supports full aggregation, but if choosing between the two exposed options for two
reserving categories, prefers option 2.

See NY comment letter: supports option 1, with additional category for “other” for any other contract with
supporting assets such that there is greater reinvestment and longevity risks, than disintermediation risk and other
risks associated with policyholder behavior as of the valuation date.

The reserving categories for VM-22 are not included in Scope. Recommend including the defined reserving
categories in the section when outlining Scope.

Page 11: [27] Commented [X121] ACLI
We would support reworking this section to rely on principles, rather than definitions to determine what is in and
out of scope. As product innovation continues, a simple list may not appropriately accommodate the applicability
of this chapter. However, if such a list is included, then we believe it should align with the full list presented in
Section 13.

ACLI will follow up with a proposed revision to the definitions and scope section

Edits to address this comment will be reflected in next exposure

suggest numbering the paragraphs within this section

Page 11: [31] Commented [CD129] CA DOI 12/30/2021 3:27:00 PM
suggest swapping the order of this section. That is, start with the "in scope" list, rather than the "out of scope" list.
Also, it seems like there should be specific mentions of GMDBs and GLBs, as there are in VM-21, since those
guarantees can also be found on FIAs.

Edits to address this comment will be reflected in next exposure

Page 11: [33] Commented [X131] TDI 11/9/2021 9:12:00 AM
Since buffer annuities are a subset of RILA, recommend deleting buffer annuities.

should this be "Non-Variable Annuity"? Otherwise, should "Fixed Annuity" be defined in the Definitions section?

Edits to address this comment will be reflected in next exposure

Page 11: [47] Commented [CD149]   CA DOI  12/30/2021 3:31:00 PM
for consistency, make plural; i.e., change to "ies"

Edits to address this comment will be reflected in next exposure

Need to clarify what is meant by “VM-22 PBR Requirements”. Add specific section references, or update proposal to have the PBR and non-PBR sections of this VM-22 draft in different chapters. After having reviewed, we think it would be much more clear to reconsider the use of "VM-23" for the PBR requirements to avoid ambiguity around scope/exclusions. The non-PBR sections also just don’t seem to fit in this draft, and there is now ambiguity around whether other parts of VM-22 apply to them (scope, effective date, principles, etc.).

Can a company wait until the end of the transition period to start PBR, but then apply PBR to the issues from during the transition period? This was unclear for VM-20, and still seems unclear here. Need to be explicit one way or the other.

Discussed with Subgroup and decided to keep the VM-22 language silent on this issue, similar to VM-20, leaving it to be determined on a case-by-case basis for each state.

The term "Deterministic Certification Option" may be confusing, as there is no "deterministic" reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the phrasing to "with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E."

Recommend replacing “the scenario reserve” with “the deterministic reserve”. Note that we also disagree with calling the deterministic reserve a stochastic reserve (later in draft), which adds a good deal of confusion.

suggest expanding header to "Stochastic Exclusion Test", for clarity

Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest rates should be broader, if even necessary. Suggest editing as:

"these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A, and VM-C, and with the statutory maximum valuation rate for immediate annuities specified in Section 13."

Edits to address this comment will be reflected in next exposure

Suggest rewording to just say "the stochastic exclusion test". There is only 1 SET, with 3 ways of passing it. Therefore, the current wording is confusion because it suggests that there are multiple SETs.

Edits to address this comment will be reflected in next exposure
Edits to address this comment will be reflected in next exposure

Page 15: [60] Commented [X188] ACLI
We believe this guidance note is unnecessary as the intent of the section is clear, and the wording is possibly confusing.

Page 15: [61] Commented [X189] TDI 11/9/2021 9:57:00 AM
The statement in this section is not acceptable as discussed in the previous TX comment letter. This will have the effect of potentially masking blocks that need PBR.

Subgroup agreed that wording for exclusion test aggregation should be consistent with VM-20. Edits to address this comment will be reflected in next exposure

Page 15: [63] Commented [X191] ACLI
This section seems to indicate that the grouping of contracts in exclusion testing should be the same as the grouping of contracts for aggregation. This might cause fewer product types to be qualifying for exclusion if the test must be performed at a higher level of aggregation.

Subgroup voted to use wording consistent with VM-20, which prohibits aggregating contracts with significantly different risk profiles.

Page 15: [65] Commented [CD193] CA DOI 12/30/2021 3:42:00 PM
for clarity, change this reference to "Section 3.D"

Edits to address this comment will be reflected in next exposure

again, suggest rewording this to just say "the stochastic exclusion test"

Edits to address this comment will be reflected in next exposure

Subgroup agreed that wording for exclusion test aggregation should be consistent with VM-20. Edits to address this comment will be reflected in next exposure.

Page 15: [70] Commented [X199] ACLI
Either in this item or in Section 12 allocation to contracts not covered by PBR methodology in VM-22 needs to be addressed e.g., carve out because reserves calculated on seriatim formulaic basis.
Edits to address this comment will be reflected in next exposure

Page 15: [72] Commented [X201]  ACLI
This sub-section seems more appropriate in Section 4 (or pulled out completely and consolidated within "I. Introduction" or "VM-01" and applied to all PBR methods).

Page 15: [73] Commented [VM22202R201]  VM-22 Subgroup  7/16/2022 9:57:00 PM
The Subgroup decided to focus solely on VM-22 for now and hold off exploring on common principles and assumptions sections

Page 15: [74] Commented [CD203]  CA DOI  12/30/2021 3:43:00 PM
VM-21 Section 3.H on simplifications, approximations, and modeling efficiency techniques is missing (including the Guidance Note). Would it make sense to add it?

Edits to address this comment will be reflected in next exposure

Page 15: [76] Commented [X206]  TDI  11/9/2021 9:59:00 AM
Recommend to periodically review at least every three years.

Page 15: [77] Commented [CD207]  CA DOI  12/30/2021 3:45:00 PM
Should this be "the company... shall", rather than the "qualified actuary... shall"? Not sure why this particular task falls on the QA, when "the company" generally has responsibility for PBR and, in the subsection directly before this one, the company is assigned the task of establishing prudent estimate assumptions.

Edits to address this comment will be reflected in next exposure

Page 15: [79] Commented [X209]  ACLI
Suggest replacing “If the results of statistical testing or other testing” with “If the results of the review” to simplify language and avoid possible confusion.

Edits to address this comment will be reflected in next exposure

Page 15: [81] Commented [X211]  TDI  11/9/2021 10:01:00 AM
Recommend replacing “the qualified actuary” with “the Company” consistent with general PBR requirements that the company set assumptions.

Edits to address this comment will be reflected in next exposure
Page 15: [83] Commented [CD213]  CA DOI  12/30/2021 3:48:00 PM
should this be “the company”? See prior comment.

Edits to address this comment will be reflected in next exposure.

Page 34: [85] Commented [VM22373]  VM-22 Subgroup  7/5/2022 4:21:00 PM
New language drafted by select Subgroup Members to provide certain conditions under which SPIA contracts could automatically pass the exclusion test.

Page 34: [86] Commented [CD374]  CA DOI  12/30/2021 4:11:00 PM
Suggest renaming this section header/name to "Requirements to Pass the SET". There is only 1 SET, but 3 ways to pass it (SERT, Demonstration or Certifications). The language gets confusing (here and elsewhere) when you start saying there are different "types" of SETs.

Page 35: [87] Commented [X378]  ACLI
We recommend removing "pension risk transfer business" from products scoped out of SET certification method. It is unclear why this business would be treated differently from individually issued business for testing intended to capture interest rate risk.

Page 35: [88] Commented [VM22379R378]  VM-22 Subgroup  3/2/2022 2:51:00 PM
Subgroup voted to keep PRT ineligible for the Certification Method.

what is meant by "aggregate risk levels"? Aggregated across what? Need clarification on the intentions for adding this phrase, when it is not in VM-20. Otherwise, I would suggest deleting this.

Edits to address this comment will be reflected in next exposure.

Page 35: [94] Commented [X388]  TDI  11/18/2021 9:49:00 PM
This is not in VM-20 and would substantially change the exclusion. The intent is not to allow you to group a block that has material interest rate risk with a larger block that is insensitive to interest rate risks and thereby pass. If "aggregate" referred to potential potting of interest rate, longevity, or asset risk then this could be redrafted to clearly call out a 4th category of risk due to a combination of the first three. However, I think this is already implicitly covered.

© 2022 National Association of Insurance Commissioners
As written, the SERT assumes a single premium product given the change of the denominator to the scenario reserve. Alternative product designs (such as longevity swap) could result in unintended results. We recommend maintaining consistency with VM-20 and using a denominator of future benefits (annuity payments, DBs, etc., excluding premium considerations, expenses, etc.).

Consensus to use a denominator that only includes benefits and expenses, consistent with VM-20

Page 35: [110] Commented [X409] TDI 11/18/2021 9:53:00 PM
Using (a) in the denominator instead of VM-20’s (c) which is a PV of benefits could make this ratio unstable when the scenario reserve (a) is very small. This is particularly applicable if the block being tested does not have CSV.

Consensus to use a denominator that only includes benefits and expenses, consistent with VM-20

Page 35: [112] Commented [X411] TDI 11/18/2021 9:59:00 PM
The variability should be assured to be immaterial based on the company’s materiality standard.

The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met July 13, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Vincent Tsang (IL); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Rachel Hemphill and Yujie Huang (TX); Tomasz Serbinowski (UT); and Craig Chupp (VA).

1. Reviewed the Updated VM-22 Subgroup Documents

Mr. Slutsker said the drafting discussion log (Attachment Twenty-A) has been updated to include the decisions from the Subgroup’s June 29 meeting.

2. Reviewed Tier Three Comments in the Proposed VM-22 Framework

Mr. Slutsker reviewed the tier three comments on the proposed VM-22 framework (Attachment Twenty-B). He said the American Council of Life Insurers (ACLI) comment on principle #3 suggested deleting the sentence that begins “Generally assumptions are ...” because it does not provide guidance. He said he is inclined to retain the wording because it also appears in VM-21, Requirements for Principle-Based Reserves for Variable Annuities. The ACLI also suggested deleting the sentence beginning “Therefore the use of assumptions ...” in principle #5. Mr. Carmello and Ms. Hemphill recommended retaining the wording for principle #3; Ms. Hemphill and Mr. Reedy recommended retaining the wording in principle #5. The Subgroup agreed to retain both sets of wording.

The California Department of Insurance (DOI) recommended adding “and Risks not Reflected” to the title of Section 1.C to be consistent with VM-21 and to appropriately describe the content of the subsections under the title. The Subgroup agreed to the title change but chose to delete Section 1.C.3 because a portion is unnecessary, and the remainder is redundant. Mr. Chupp noted that a similar change to VM-21 should be considered.

The California DOI recommended removing references to “separate account fund performance” in Section 1.C.2.a and other places because non-variable annuities are not known to have separate accounts. Rhonda Ahrens (Thrivent) asked if modified guaranteed annuities are considered variable or non-variable products. She said she is not aware of any requirement that would prohibit a non-variable product from having a separate account fund. Ms. Lam said the comment was intended to align this section with other sections where references to separate account funds were deleted. Mr. Leung said that if index-linked variable annuities will be covered by VM-22, the references to separate account funds will have to be retained. Mr. Slutsker said that the reference to separate account funds will be retained, but a guidance note soliciting feedback on the matter will be added.

The Texas Department of Insurance (TDI) recommended changing the wording in Section 1.C.4.a to its original wording, “run on the bank,” to be consistent with the wording in VM-21.

The ACLI commented that Section 1.C.4.b.iv is extraneous and should be deleted. The Subgroup said that without a clear reason why the language should be removed, the language will be retained to maintain consistency with VM-21.

The Subgroup agreed that the term “fixed annuity” should be replaced by the term “non-variable annuities” throughout the proposed VM-22 framework.
The Subgroup discussed whether registered indexed-linked annuities (RILAs) should be subject to the requirements of VM-22 or VM-21. There was not a clear preference among Subgroup members. The Academy said RILAs should be addressed in VM-21. Mr. Leung said it should be clarified that non-registered indexed-linked annuities, such as fixed indexed annuities, are addressed in the proposed VM-22 framework. The Subgroup agreed to use the term index-linked variable annuities (ILVAs), instead of RILAs, to be consistent with the name of the Index-Linked Variable Annuity (A) Subgroup.

Ms. Lam agreed to retract the California DOI comment asking to retain the definition of cash value because it is defined in VM-01, Definitions. She assented to the deletion of the definition of guaranteed minimum death benefit (GMDB) from the proposed VM-22 framework if the GMDB definition in VM-21 is moved to VM-01.

Having no further business, the VM-22 (A) Subgroup adjourned.

Section 1: Background

A. Purpose

Sections 1 through 13 of these requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2024. Section 14 of these requirements establish the maximum valuation rate for payout annuities for contracts issued on or after 1/1/2018. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CRVM) and, for certain contracts and certificates, the Commissioners Reserve Valuation Method (CRVM).

Guidance Note: CRVM requirements apply to some group pension contracts.

Relationship to RBC Requirements

These requirements anticipate that the projections described herein are used for the determination of RBC for all of the contracts falling within the scope of these requirements. These requirements and the RBC requirements for the topics covered within Sections 4.A through 4.E are identical. However, while the projections described in these requirements are performed on a basis that ignores federal income tax, a company may elect to conduct the projections for calculating the RBC requirements by including projected federal income tax in the cash flows and reducing the discount interest rates used to reflect the effect of federal income tax as described in the RBC requirements. A company that has elected to calculate RBC requirements in this manner may not switch back to using a calculation that ignores the effect of federal income tax without approval from the domiciliary commissioner.

Guidance Note: The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

Principle 1: The objective of the approach used to determine the stochastic reserve SR is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

Principle 2: The calculation of the stochastic reserve SR is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cash-
flow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions and reserving categories) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve SR at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

**Guidance Note:** Examples where full aggregation between contracts may not be possible include experience rated group contracts and the operation of reinsurance treaties.

**Principle 3:** The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the stochastic reserve SR at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve SR, the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

**Guidance Note:** The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle. More guidance and requirements for setting assumptions in general are provided in Section 12.

**Principle 4:** While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve SR is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

**Principle 5:** Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve SR. Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve SR without also reducing risk on scenarios similar to those used...
in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

C. Risks Reflected

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and
   b. Capable of materially affecting the reserve.

2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
      i. Credit risks (e.g., default or rating downgrades).
      ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).
      iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).
      iv. Performance of equities, real estate, and Schedule BA assets.
      v. Call risk on callable assets.
      vi. Separate account fund performance.
      vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).
      viii. Currency risk.
   b. Liability risks
      i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.
      ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.
      iii. Utilization risk associated with guaranteed living benefits.
      iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.
v. Annuityization risks.

vi. Additional premium dump-ins or deposits [high interest rate guarantees in low interest rate environments].

vii. Applicable expense risks, including fluctuation in maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks

i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.

ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).

iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:

a. Those not associated with the policies or contracts being valued, or their supporting assets.

b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:

a. Asset risks

i. Liquidity risks associated with a sudden and significant levels of withdrawals and surrenders “run on the bank.”

b. Liability risks

i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.

ii. Catastrophic events (e.g., epidemics or terrorist events).

iii. Major breakthroughs in life extension technology that have not yet fundamentally-altered recently observed mortality experience.

iv. Significant future reserve increases as an unfavorable scenario is realized.

c. General business risks

i. Deterioration of reputation.
ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.

iii. Poor management performance.

iv. The expense risks associated with fluctuating amounts of new business.

v. Risks associated with future economic viability of the company.

vi. Moral hazards.

vii. Fraud and theft.

viii. Operational.

ix. Litigation.

D. Specific Definitions for VM-22

**Buffer Annuity**
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

- **Deferred Income Annuity (DIA)**
  An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin 13 months or later after (or from) the issue date if the contract holder survives to a predetermined future age.

- **Fixed Indexed Annuity (FIA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, subject to certain limits, typically with guaranteed principal.

- **Flexible Premium Deferred Annuity (FPDA)**
  An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

- **Funding Agreement**
  A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

- **Guaranteed Investment Contract (GIC)**

---

Commented [VM2254R53]: We suggest clarifying the definition of "Guaranteed Investment Contract (GIC)" to make it more specific and relevant to the scope of VM-22.

Commented [VM2266R65]: It seems the definitions included in the document are largely only used for the purpose of establishing the Scope in Section 2. Since this is intended to be a principles-based methodology, recommend a more specific definition of "Guaranteed Investment Contract (GIC)" instead of specific products and terms used in this business. The first paragraph in A. Scope seems to provide this with specific references which are not repeated in the subsequent paragraphs. If changing the scope section, we would suggest deleting the various product definitions if not useful elsewhere. If these definitions are potentially applicable beyond VM-22, we would suggest moving any necessary definitions to VM-22.

Commented [VM2252R51]: No objections from the Subgroup to an approach that is broader and focuses less on definitions. ACL will follow-up with proposed revisions to the scope section.

Commented [CD53]: The format of this Definition section is consistent with other parts of the VM in VM-12 and VM-21, each defined term is numbered, and is defined in this format (example).

Commented [VM2254R53]: Edits to address this comment will be reflected in next exposure.

Commented [X55]: The term "Buffer Annuity" is not interchangeable with the "Registered Index-Linked Annuity (RILA)" as defined in Section 1.D. and the term "buffer annuity" is interchangeable with the term "registered index-linked annuity (RILA)", as defined in Section 1.D. (5).

Commented [VM2256R55]: Edits to address this comment will be reflected in next exposure.

Commented [X57]: The term "Buffer Annuity" is not interchangeable with the "Registered Index-Linked Annuity (RILA)" as defined in Section 1.D. and the term "buffer annuity" is interchangeable with the term "registered index-linked annuity (RILA)", as defined in Section 1.D.

Commented [VM2255R53]: Edits to address this comment will be reflected in next exposure.

Commented [X59]: The wording "after (or from) the issue date" used in the DIA and SPIA definitions is confusing. Recommend keeping it simple as "from" the issue date.

Commented [VM2260R59]: Edits to address this comment will be reflected in next exposure.

Commented [X61]: It "typically" intended to be a periodic interest rate definition. It is assumed that it does not need to be guaranteed principal.

Commented [VM2262R61]: Edits to address this comment will be reflected in next exposure.

Commented [CD63]: Insert: "subject to certain limits.,".

Commented [VM2264R63]: Edits to address this comment will be reflected in next exposure.

Commented [X65]: The definition of DIA describes the account value it typically with guaranteed principal.

Commented [VM2266R65]: Edits to address this comment will be reflected in next exposure.
Insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

- **Index Credit Hedge Margin**
  A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

- **Index Credit**
  Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to contract values that is linked to an index or indices. Amounts credited to the contract resulting from a floor on an index account are included.

- **Index Crediting Strategy**
  The strategy defined in a contract to determine index credits for a contract. This refers to an underlying index, index parameters, date, timing, performance triggers, and other elements of the crediting method.

- **Index Parameter**
  Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

- **Longevity Reinsurance**
  An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

- **Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or on a pre-specified period of time, and these agreements may or may not permit early termination.

- **Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of...**

Commented [VM2276R75]: VM-22 Subgroup has exposed a proposal from NJ to address this issue.
a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

- **Market Value Adjustment (MVA) Annuity**
  An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

- **Modified Guaranteed Annuity (MGA)**
  A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values and death benefits that are based upon a market-value adjustment formula if held for shorter periods.

- **Multiple Year Guaranteed Annuity (MYGA)**
  A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

- **Pension Risk Transfer (PRT) Annuity**
  An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

- **Registered Index-Linked Annuity (RILA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

- **Single Premium Immediate Annuity (SPIA)**
  An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within 13 months one year after (or from) the issue date.

- **Single Premium Deferred Annuity (SPA)**
  An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.
• **Stable Value Contract**
  A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

• **Structured Settlement Contract (SSC)**
  A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

• **Synthetic Guaranteed Investment Contract (Synthetic GIC)**
  Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the contract policyholder or plan trust.

• **Term Certain Payout Annuity**
  A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

• **Two-Tiered Annuity**
  A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.

The term “cash surrender value” means, for the purposes of these requirements, the amount available to the contract holder upon surrender of the contract. Generally, it is equal to the account value less any applicable surrender charges, where the surrender charge reflects the availability of any free partial surrender options. However, for contracts where all or a portion of the amount available to the contract holder upon surrender is subject to a market value adjustment, the cash surrender value shall reflect the market value adjustment consistent with the required treatment of the underlying assets. That is, the cash surrender value shall reflect any market value adjustments where the underlying assets are reported at market value, but it shall not reflect any market value adjustments where the underlying assets are reported at book value.

The term “guaranteed minimum death benefit” (GMBD) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount; or (ii) exceeds the minimum amount and is increased by an amount that may be either specified by or computed from other policy or contract values; and
has the potential to produce a contractual total amount payable on such death that exceeds the account value or
in the case of an annuity providing income payments, guaranteed payment upon such death of an amount payable on death in addition to the continuation of any guaranteed income payments.

E. Materiality

The company shall establish a standard containing the criteria for determining whether an assumption, risk factor, or other element of the principle-based valuation has a material impact on the size of the reserve. This standard shall be applied when identifying material elements.

Section 2: Scope and Effective Date

A. Scope

Subject to the requirements of this Section 1 to 13 of VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities, RIIAs, buffer annuities, and structured annuities)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

Products in scope of VM-22 include non-variable annuities which consist of, but are not limited to, the following list:

- **Account Value Based Annuities**
  1. Deferred Annuities (SPDA & FPDA)
  2. Multi-Year Guarantee Annuities (MYGA)
  3. Fixed Indexed Annuities (FIA)
  4. Market Value Adjustments (MVA)
  5. Two-tiered Annuities
  6. Guaranteed/Benefits/Riders on Non-Variable Annuity Contracts

- **Payout Annuities**
  1. Single Premium Immediate Annuities (SPIA)
  2. Deferred Income Annuities (DIA)
  3. Term Certain Payout Annuities
  4. Pension Risk Transfer Annuities (PRT)
  5. Structured Settlement Contracts (SSC)
  6. Longevity Reinsurance
Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities and RILAs)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.

B. Effective Date & Transition

Effective Date

These requirements apply for valuation dates on or after January 1, 2024.

Transition

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the first three years following the effective date of VM-22 PBR. If a company during the three-year transition period elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve SR (following the requirements of Section 4) plus the additional standard projection amount (following the requirements of Section 6) plus the DR for those contracts satisfying the Deterministic Certification Option, less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

Guidance Note: Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves SR, per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined: The Additional Standard Projection Amount

D. The Stochastic Reserve

The additional standard projection amount is determined by applying one of the two standard projection methods defined in Section 6. The same method must be used for all contracts within a group of contracts that are aggregated together to determine the reserve. The company shall elect which method they will use to determine the additional standard projection amount. The company may not change that election for a future valuation without the approval of the domiciliary commissioner.

E. The SR

1. The SR shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.G herein.

2. The stochastic reserve SR amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve DR following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts within each Reserving Category as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles: SR. However, groups of contracts within different Reserving Categories may...
not be aggregated together in determining the SR. For the purposes of VM-22, Reserving Categories are classified as the following:

a. The “Payout Annuity Reserving Category” includes the following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits provided by variable annuities:
   i. Immediate annuity contracts;
   ii. Deferred income annuity contracts;
   iii. Structured settlements in payout or deferred status;
   iv. Fixed income payment streams resulting from the exercise of settlement options or annuitizations of host contracts issued;
   v. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest);
   vi. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts, once the contract funds are exhausted;
   vii. Certificates, emanating from non-variable group annuity contracts specified in Model #820, Section 3.C.2, purchased for the purpose of providing certificate holders fixed income payment streams upon their retirement; and
   viii. Pension Risk Transfer Annuities; and
   ix. Longevity Reinsurance.

b. The “Accumulation Reserving Category” are all annuities within scope of VM-22 under Section II of the NAIC Valuation Manual that are not in the “Payout Reserving Category”.

Drafting Note: Additional feedback is welcome for whether to permit optionality for categorizing guaranteed living benefit contracts with depleted fund value as either in the payout or accumulation reserving category.

Commented [VM22163]: Include deferred annuities in deferred annuity category.

Commented [VM22164R163]: The Subgroup has elected to leave these contracts in the payout annuity reserving category, but is adding to a drafting note to welcome feedback.
4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

5a. To the extent that these limits on the aggregation results in more than one model segment, the stochastic reserves SR shall equal the sum of the stochastic reserves SR amounts computed for each model segment and the actuarial reserve DR amounts computed for each model segment for which the company elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test

1. To the extent that certain groups of contracts pass one of the defined stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for immediate annuities specified in Section 13. These groups of contracts may be valued using the methodology and statutory maximum valuation rate for immediate annuities specified in Section 13 of Model #820 and must periodically at least every 3 years review and update the assumptions as appropriate in accordance with these requirements.

2. The approach for grouping contracts that may not group together contract types with significantly different risk profiles when performing the exclusion test should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserves in Section 13 above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of the requirements using the method outlined in Section 4213, with the exception of contract following Section 5.E which are to be calculated on a small basis.

G. Prudent Estimate Assumptions

1. With respect to the Stochastic Reserves SR in Section 3.D.C, the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements in Section 12 of Model #820 and must periodically at least every 3 years review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary Company shall set a new, adequate, anticipated experience assumption for the factor.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018, AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on/after 2018, Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

5-627

© 2022 National Association of Insurance Commissioners 15
3. To determine the prudent estimate assumptions, the stochastic reserve (SR) shall also follow the requirements in Sections 4 and general assumptions including Section 9 for asset assumptions, Section 10 for contract/policy holder behavior assumptions, and Section 11 for mortality assumptions, and Section 12 for general guidance and expense assumptions.

H. Approximations, Simplifications, and Modeling Efficiency Techniques

A company may use simplifications, approximations, and modeling efficiency techniques to calculate the SR and/or the additional standard projection amount required by this section if the company can demonstrate that the use of such techniques does not understate the reserve by a material amount, and the expected value of the reserve calculated using simplifications, approximations, and modeling efficiency techniques is not less than the expected value of the reserve calculated that does not use them.

Guidance Note:

Examples of modeling efficiency techniques include, but are not limited to:

1. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters.
2. Generating a smaller liability or asset model to represent the full seriatim model using grouping compression techniques or other similar simplifications.

There are multiple ways of providing the demonstration required by Section 3.H. The complexity of the demonstration depends upon the simplifications, approximations or modeling efficiency techniques used. Examples include, but are not limited to:

1. Rounding at a transactional level in a direction that is clearly and consistently conservative or is clearly and consistently unbiased with an obviously immaterial impact on the result (e.g., rounding to the nearest dollar) would satisfy 3.H without needing a demonstration. However, rounding to too few significant digits relative to the quantity being rounded, even in an unbiased way, may be material and in that event, the company may need to provide a demonstration that the rounding would not produce a material understatement of the reserve.
2. A brute force demonstration involves calculating the minimum reserve both with and without the simplification, approximation or modeling efficiency technique, and making a direct comparison between the resulting reserve. Regardless of the specific simplification, approximation or modeling efficiency technique used, brute force demonstrations always satisfy the requirements of Section 3.H.
3. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters and providing a detailed demonstration of why it did not understate the reserve by a material amount and the expected value of the reserve would not be less than the expected value of the reserve that would otherwise be calculated. This demonstration may be a theoretical, statistical or mathematical argument establishing, to the satisfaction of the insurance commissioner, general bounds on the potential deviation in the reserve estimate rather than a brute force demonstration.
4. Justify the use of randomly sampling withdrawal ages for each contract instead of...
following the exact prescribed WDCM method by demonstrating that the random sampling method is materially equivalent to the exact prescribed approach, and the simplification does not materially reduce the Additional Standard Projection Amount and the final reported reserve. In particular, the company should demonstrate that the statistical variability of the results based on the random sampling approach is immaterial by testing different random sets, e.g., if randomly selecting a withdrawal age for each contract, the probability distribution of the withdrawal age should be stable and not vary significantly when using different random number sets.

Commented [X203]: Specific example should be tailored based on the SPA developed.

Commented [X204]: Added consistent with VM-21 Section 3.H, which was added to the 2022 VM.

Commented [VM22205R204]: Edits to address this comment will be reflected in next exposure.
Section 4: Determination of Stochastic Reserve SR

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Sections 4 and 9. The company shall project cash flows including the following:

a. **Revenues** Gross premium received by the company including gross premiums received from the policyholder, policyholder (contract holder) (including any due premiums as of the projected start date).

**Guidance Note:** If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset.

b. Other revenues, including contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).

c. All material benefits projected to be paid to contract holders—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.

**Guidance Note:** Amounts charged to account values on general account business are not revenues, examples include rider charges and expense charges.

d. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.1.

ed. Insurance company expenses (including overhead and investment maintenance expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses), other acquisition expenses, associated with business in force as of the valuation date.

efe. **Net Cash flows associated with any reinsurance.**

dg. Cash flows from hedging instruments as described in Section 4.4.4.
Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.

**Guidance Note**: Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance).

**Guidance Note**: Section 4.A.1 requires market value adjustments (MVAs) on liability cash flows to be reflected because in a cash flow model, assets are assumed to be liquidated at market value to cover the cash outflow of the cash surrender; therefore, inclusion of the market value adjustment aligns the asset and liability cash flows. This may differ from the treatment of MVAs in the definition of cash surrender value (Section 1.D), which defines the statutory reserve floor for which the values must be aligned with the annual statement value of the assets.

2. **Grouping of Index Crediting Strategies**

Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

3. **Model Cells**

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.
4. Modeling of Hedges

a. For a company that does not have a future hedging program but directly supports the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

   a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or
   b) No hedge positions—in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program but directly supports the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

   a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders.

   b) Existing hedging instruments that are currently held by the company for the purpose of offsetting the indexed credits in support of the contracts falling under the scope of these requirements shall be included in the starting assets. Existing hedging instruments that are currently held by the company not for any other purpose offsetting the indexed credits should be modeled consistently with the requirements of Section 4.4.4.a.ii.

   c) An Index Credit Hedge Margin for these hedge instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible

Commented [X230]: Given that Section 9 covers hedging, we would suggest considering moving parts of Section 4.4.4 to that section.

Commented [X231]: VM-22 took out the CHDS requirement and replaced it with “future hedging program”. Future hedging should not materially reduce reserves or TAR if it is not well documented. The hedging DG is currently working on this for VM-20/VM-21. We will work with VM-22 subgroup to edit VM-22 accordingly.

Commented [X232]: Suggest rewording “Future hedging program” to “hedging program with future transactions” to avoid ambiguity.

Commented [CD233]: The word “future” to describe the “hedging program” here is confusing. What about current hedging programs with expected future hedge purchases? Why not just say “hedging program”? Also, I wanted to note that removing the concept of CHDS creates inconsistency with both VM-20 and VM-21. Why not retain it?

Commented [CD234]: same comment as above, about the word “future” being confusing

Commented [CD235]: [contract holders]

Commented [VM22236R235]: Edits address this comment will be reflected in next exposure

Commented [X237]: [Any other purpose” in the last sentence seems overly broad and should be narrowed

Commented [VM22238R237]: Edits address this comment will be reflected in next exposure

Commented [X239]: Specify “for this purpose” as “for offsetting the indexed credits” as “not for offsetting the indexed credits”.

Commented [VM22240R239]: Edits address this comment will be reflected in next exposure

Commented [X241]: [a] Ensure that the margin is based on the expected

Commented [CD242]: Further, we believe the comment should be.

Commented [VM22242R241]: Subgroup agreed to revisit this discussion after field testing.

Commented [CD243]: Clarify verbiage by saying “hedging instruments” or “derivative instruments”.

Commented [VM22244R243]: Edits address this comment will be reflected in next exposure
company experience and be no less than \([X\%]\) multiplicatively of the interest credited. In the absence of sufficient and credible company experience, a margin of \([Y\%]\) shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than \([Y\%]\). It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements:

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve \(SR\). The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future. Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve \(SR\) as the weighted average of two CTE values; first, a CTE70 (“best efforts”) representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE70 (“adjusted”) which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i.m, if the company has an indexed credit hedging program, the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.i.ca in both the “best efforts” run and the “adjusted” run.

d) The use of products not falling under the scope of Section 1 through 13 requirements (e.g., variable annuities, equity-indexed annuities) as a hedge shall not be recognized in the determination of accumulated deficiencies.

Guidance Note: Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other hedging from other hedging. In this case the hedge positions are considered similarly to other...
5. Revenue Sharing

If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each as defined in Section 4.A.5.a through 4.A.5.f as met.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods. Obligations remain at the end of the projection periods. Company can choose to run a shorter projection period but not shorter than 20 years and include the present value of the terminal benefits and expenses in the accumulated deficiency calculation.

7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. For a given scenario, the scenario reserve shall be determined using one of two methods described below:

   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defasement of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period.

Guidance Note: The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.
The scenario reserve for any given scenario shall not be less than the cash surrender value 
with market value adjustment in aggregate on the valuation date for the group of contracts
modeled in the projection.

2. Discount Rates

In determining the scenario reserve, unless using the direct iteration method pursuant to 
Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on 
additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

a. The additional invested asset portfolio for a scenario is a portfolio of general 
account assets as of the valuation date, outside of the starting asset portfolio, that 
is required in that projection scenario so that the projection would not have a 
positive accumulated deficiency at the end of any projection year. This portfolio 
may include only (i) General Account assets available to the company on the 
valuation date that do not constitute part of the starting asset portfolio; and (ii) cash 
assets.

Guidance Note:

Additional invested assets should be selected in a manner such that if the starting asset portfolio were 
revised to include the additional invested assets, the projection would not be expected to experience any 
positive accumulated deficiencies at the end of any projection year.

It is assumed that the accumulated deficiencies for this scenario projection are known.

b. To determine the NAER on additional invested assets for a given scenario:

   i. Project the additional invested asset portfolio as of the valuation date to 
      the end of the projection period,
      a) Investing any cash in the portfolio and reinvesting all investment 
         proceeds using the company’s investment policy.
      b) Excluding any liability cash flows.
      c) Incorporating the appropriate returns, defaults and investment 
         expenses for the given scenario.

   ii. If the value of the projected additional invested asset portfolio does not 
      equal or exceed the accumulated deficiencies at the end of each projection 
      year for the scenario, increase the size of the initial additional invested 
      asset portfolio as of the valuation date, and repeat the preceding step.

   iii. Determine a vector of annual earned rates that replicates the growth in the 
       additional invested asset portfolio from the valuation date to the end of the
projection period for the scenario. This vector will be the NAER for the given scenario.

iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.c, as a safe harbor.

Guidance Note: There are multiple ways to select the additional invested asset portfolio at the valuation date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

Treasury Department interest rate curves, as well as investment return paths for index funds, equities, and fixed income assets shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.

D. Projection of Assets

1. Starting Asset Amount

a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:

i. Any hedge instruments held in support of the contracts being valued; and

ii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i).

b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described...
above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets

For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

Guidance Note: Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets

a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:

i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;

ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the modeled company investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results

Commented [X272]: This change was adopted for VM-20

Commented [VM2273R272]: Edits to address this comment will be reflected in next exposure

© 2022 National Association of Insurance Commissioners

in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the modeled aggregate reserve shall be the higher of that produced by the modeled company investment strategy and any non-prescribed asset spreads. It shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained by substituting an alternative investment strategy in which all fixed income reinvestment assets have the same weighted average life (WAL) as the reinvestment assets in the modeled company investment strategy and are all public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 20% PBR credit rating 3 (Aa2/AA)

iii. 40% PBR credit rating 6 (A2/A)

iv. 40% PBR credit rating 9 (Baa3/BBB)

c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.ii; and Section 4.D.4.a.iv, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.

Guidance Note: This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets
   a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:
   
   ...
i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F, as noted in 4.a.ii above.

b. Cash flows from general account-index funds and general account equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.H.

E. Projection of Annuity Benefits

1. Assumed Annuity Purchase Rates

a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such purchase rates shall reflect the payout rate specified in the contract.

b. For purposes of projecting future elective annuity payments (including annuities stemming from the election of a GMIB) and withdrawal amounts from GMWBs, the projected annuity purchase rates shall be determined.
When determining a stochastic reserve SR, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve, additional standard projection amount the SR, DR, and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both a pre-reinsurance ceded and a post-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

Reflection of Reinsurance Cash Flows in the DR or SR:

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve SR and DR shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This includes including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

i. In this section, reinsurance includes retrocession, and assuming company includes retrocessionaire.

ii. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

iii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iv. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the stochastic reserve if it qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum aggregate reserve by the absolute value of such reductions in surplus.
b. In order to determine the stochastic reserve (SR) and deterministic reserve (DR) on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve (SR) and deterministic reserve (DR) shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard reinsurance treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection based on using starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable method.

Guidance Note: For standard pro rata insurance treaties (do not include experience refunds), where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld in excess of proportionate share; modified coinsurance; coinsurance with a trust. To the extent these assets were available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard coinsurance treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, *Principle-Based Reserves for Life Products under the NAIC Valuation Manual*, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsured policies belong and reflect the terms of the reinsurance agreement.

d. The company shall assume that the counterparties to a reinsurance agreement are knowledgeable about the contingencies involved in the agreement and likely to exercise the terms of the agreement to their respective advantage, taking into account the context of the agreement in the entire economic relationship between the parties. In setting assumptions for the NGE in reinsurance cash flows, the company shall include, but not be limited to, the following:

i. The usual and customary practices associated with such agreements,

ii. Past practices by the parties concerning the changing of terms, in an economic environment similar to that projected,

iii. Any limits placed upon either party’s ability to exercise contractual options in the reinsurance agreement,

iv. The ability of the direct-writing company to modify the terms of its policies in response to changes in reinsurance terms,

v. Actions that might be taken by a party if the counterparty is in financial difficulty.

3. Reserve Determined Upon Passing the Exclusion Test
If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance-ceded and post-reinsurance-ceded reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance-ceded reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance-ceded reserves might not, or vice versa.

4. Additional Standard Projection Amount

Where reinsurance is ceded, the additional standard projection amount shall be calculated as described in Section 6 to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties. The additional standard projection amount shall also be calculated pre-reinsurance ceded using the methods described in Section 6 but ignoring the effects of the reinsurance ceded.
Section 6: Standard Projection Amount To Be Determined

Commented [VM22339]: NY Comment Letter: Current CARVM standards should be a minimum floor for VM-22 policies, and only the stochastic reserve should permit grouping whereas the minimum floor should be seriatim.

Commented [X340]: SPA Section placement here still makes sense, but SPA under development.

Commented [VM22342]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.

Commented [X343]: SPA section placement here still makes sense, but SPA under development.

Commented [VM22344]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.

Commented [NJ345]: Once this is written, the language from 4.4.1.a for longevity reinsurance could be added here as well, i.e. the standard projection would use net premiums based on the k factor approach, using the standard projection prescribed assumptions. Floor on std projection is at the contract level.
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve (SR) calculation if the stochastic exclusion test (SET) is satisfied for at least one group of contracts. The company has the option to calculate or not calculate the SET.

   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then for each group of contracts that passes the SET, the company shall choose whether or not to calculate the aggregate reserve for those groups of contracts.

   c. A company may not exclude a group of contracts from the stochastic reserve (SR) requirements if there are one or more future hedging programs associated with supporting the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9 A.1.

   d. A company may elect to automatically exclude one or more groups of policies from the stochastic reserve calculation without passing the stochastic exclusion test (SET) if all of the following are met for all contracts in the group or groups:

      i. All of the contracts are either:
         - Single Premium Annuities,
         - Term Certain Payout Annuities, or
         - Structured Settlement Contracts.

      ii. None of the contracts are pension risk transfer annuities (PRT) or are covered under a longevity reinsurance agreement.

      iii. Future payout benefits are either level or stay within 5% of the initial payout benefit amount over time.

      iv. There is either no or an immaterial level of policyholder options permitted within the contracts; and

      v. The average (Macaulay duration) of the liabilities of the contracts as measured from the issue date (or premium determination date) is less than \[ X \].

B. Requirement to Pass the Types of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

1850 M Street NW  Suite 300  Washington, DC 20036  Telephone 202 223 8196  Facsimile 202 872 1948  www.actuary.org

Commented [X346]: Need to modify exclusion testing section to reflect SPA.

Commented [NJ347]: Longevity reinsurance likely to be scoped out of the stochastic reserve unless the stochastic reserve includes consideration of stochastic mortality. If it stays as stochastic interest only, then it probably does make sense that it would meet the exclusion testing. For exclusion testing, the k factor approach should continue to apply, and it should not be combined with other blocks of business.

Commented [X348]: Inconsistent groups vs. group references.

Commented [VM22349R338]: Edits to address this comment will be reflected in next exposure.

Commented [CD350]: Should this be "stochastic reserve" since Section 4 is about determining the stochastic reserve.

Commented [VM22351R350]: Follow Section 4 method of stochastic reserve for Section 3 aggregate reserve if not using the SET.

Commented [X352]: Decision is independent for each group, the SET is performed on.

Commented [VM22353R352]: Edits to address this comment will be reflected in next exposure.

Commented [CD354]: Suggest deleting this highlighted part of the finding.

Commented [VM22355R354]: Edits to address this comment will be reflected in next exposure.

Commented [CD356]: See earlier comment about the phrase "future hedge program" being confusing.

Commented [X357]: Is "associated with the contracts" the same as the earlier use of "supporting the contracts"? Should the same verbage be used here? If there is asset hedging for the assets supporting the contracts, it should be included. Need to define "solely supporting" index credits, and also have criteria on the effectiveness/error and documentation of any such hedging that is allowed for excluded business.

Commented [VM22358]: The phrase "in the aggregate" should replace the verb "is" in the sentence below.

Commented [VM22359]: New language drafted by select Subgroup Members to provide certain condition.

Commented [CD360]: Suggest renaming this section header/name to "Requirements to Pass the SET". There is only 1 SET, but 3 ways to pass it (SET, Demonstration, etc.).

Commented [VM22361R360]: Edits to address this comment will be reflected in next exposure.
1. Stochastic Exclusion Ratio Test (SERT)—Annually within 12 months before the valuation date, but within 12 months before the valuation date the company demonstrates that the groups of contracts pass the SERT defined in Section 7.C.

2. Stochastic Exclusion Demonstration Test—In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.

3. SET Certification Method—For groups of contracts that do not have guaranteed living benefits, future hedging programs, or pension risk transfer business, in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts is not subject to material aggregate risk levels across interest rate risk, mortality and/or longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

Guidance Note: The qualified actuary should develop documentation to support the actuarial certification that presents his or her analysis clearly and in detail sufficient for another actuary to understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not subject to material interest rate risk, mortality and/or longevity risk, or asset return volatility risk. Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:

a) A demonstration that, using requirements under VM-A and VM-C for the group of contracts, reserves calculated using requirements under VM-A and VM-C are at least as great as the assets required to support the group of contracts and certificates using the company’s cash-flow testing model under each of the 4416 scenarios identified in this section, Section 7.C.1 or alternatively each of the New York seven scenarios economic scenarios, under each of the three mortality adjustment factors identified in Section 7.C.1.

b) A demonstration that the group of contracts passed the SERT within 36 months prior to the valuation date and the company has not had a material change in its interest rate risk, mortality and/or longevity risk, or asset return volatility risk.

c) A qualitative risk assessment of the group of contracts that concludes that the group of contracts does not have material interest rate risk, mortality and/or longevity risk, or asset return volatility risk. Such assessment would include an analysis of product guarantees, the company’s non-guaranteed elements (NGEs) policy, assets backing the group of contracts, the company’s longevity risk, and the company’s investment strategy.

C. Stochastic Exclusion Ratio Test

1. In order to exclude a group of contracts from the stochastic exclusion SR requirements under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of (b−a)/a is less than the greater of [x]%, where x is the percentage change that would trigger the company’s materiality standard, where:

Commented [CD362]: Not sure why this part is deleted
Commented [VM22363R362]: Suggest adding it back in
Commented [X364]:
Commented [VM22365R364]: Subgroup voted to delete... [73]

Commented [X395]: Consensus to use... [96]
Commented [VM22396R395]: Consensus to use... [97]
Commented [X397]: The variability should be assessed
a.  $a$ = the adjusted scenario reserve described in Paragraph 7.C.2.a.i below using economic scenario 9, and 100% as the adjustment factor for mortality, the baseline economic scenario, as described in Appendix 1.E of VM-20.

b.  $b$ = the largest adjusted scenario reserve described in Paragraph 7.C.2.a below under any of the other 1416 economic scenarios described in Appendix 1.E of VM-20 under both [95%; 100%, 100%] and [105%] of anticipated experience mortality excluding margins. Because mortality variability may differ by company, if the magnitude of the company’s margin for mortality exceeds 5%, then the company shall use the baseline mortality and the mortality augmented by plus and minus the company’s margin for this exercise.

**Guidance Note:** Note that the numerator should be the largest adjusted scenario reserve for scenario other than the baseline economic scenario, minus the adjusted scenario reserve for the baseline economic scenario, and 100% as the adjustment factor for mortality. This is not necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100% as the adjustment factor for mortality, or the absolute value of the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100% as the adjustment factor for mortality, both of which could lead to an incorrect test result. There are 47 (=16×3−1) combined economic and mortality scenarios that should be compared for the determination of $b$.

2. In calculating the ratio in subsection (Section 7.C.1) above:

a.  The company shall calculate an adjusted scenario reserve for the group of contracts for each of the 16 scenario economic factors using the three levels of mortality adjustment factors that is equal to either (i) or (ii) below:

i.  The scenario reserve defined in Section 4, but with the following differences:

   a)  Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph Section 7.C.1.b of this section.

   b)  Using the interest rates and equity return assumptions specific to each scenario.

   c)  Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.

   d)  Shall reflect future mortality improvement in line with anticipated experience assumptions.

   e)  Shall not reflect correlation between longevity and economic risks.

ii.  The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:

   a)  Using the interest rates and equity return assumptions specific to each scenario.
b) Using the mortality scalars described in Paragraph Section 7.C.1.b of this section.

c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current available baseline economic scenario and the 15 other economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.

e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the stochastic exclusion ratio test under only a pre-reinsurance-ceded single basis upon determining the either pre-reinsurance-ceded basis upon determining the post-non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurance but ignoring the non-proportional contract(s), and “net of non-proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.

3. If the ratio calculated in this section is less than [x]% pre-non-proportional reinsurance, but is greater than [x]% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation, \( SERT = \frac{(b-a)}{a} \) defined in Section 7.C.1 above

   a) The pre-non-proportional reinsurance results are “gross of non-proportional,” with a subscript “gn,” so denoted \( SERT_{gn} \)

   b) The post-non-proportional results are “net of non-proportional,” with subscript “nn,” so denoted \( SERT_{nn} \)

ii. If a block of business being tested is subject to one or more non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurance but ignoring the non-proportional contract(s), and “net of non-proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.
D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve SR requirements using the methodology in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

   a. The demonstration shall provide a reasonable assurance that if the stochastic reserve SR was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve SR exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve SR requirements.

   b. If, as of the end of any calendar year, the company determines the aggregate statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.

   c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an increase in the date underlying bₚₐ could be different from the scenario underlying bₚₐ.

   \[ \text{LPIR}_{\text{fr}} = (b_{\text{fr}} - a_{\text{fr}} + b_{\text{fr}2} - a_{\text{fr}2})/a_{\text{fr}} \]

   \[ \text{LPIR}_{\text{fm}} = (b_{\text{fm}} - a_{\text{fm}} + b_{\text{fm}2} - a_{\text{fm}2})/a_{\text{fm}} \]

   Note that the scenario underlying bₚₐ could be different from the scenario underlying bₚₐ.

   If \[ \text{SERT}_{\text{fr}} \times \text{LPIR}_{\text{fr}} / \text{LPIR}_{\text{fm}} < [\text{X}_{\text{fr}}^{20}] \], then the block of contracts passes the SERT.

b. Another more qualitative approach is to calculate the adjusted scenario reserves for the 4453 combined economic and mortality scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.

4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section; Section 7.D.2.a or Section 7. D.2.b and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

b. If, as of the end of any calendar year, the company determines the aggregate statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.

c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an increase in the date underlying bₚₐ could be different from the scenario underlying bₚₐ.

\[ \text{LPIR}_{\text{fr}} = (b_{\text{fr}} - a_{\text{fr}} + b_{\text{fr}2} - a_{\text{fr}2})/a_{\text{fr}} \]

\[ \text{LPIR}_{\text{fm}} = (b_{\text{fm}} - a_{\text{fm}} + b_{\text{fm}2} - a_{\text{fm}2})/a_{\text{fm}} \]

Note that the scenario underlying bₚₐ could be different from the scenario underlying bₚₐ.
E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve SR for a group of contracts using a single deterministic economic scenario, subject to the following conditions.
   a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies contracts and certificates. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recurring premium payments, and guaranteed living benefits.
   b. The company certifies that the group of policies contracts and certificates is not supported by a reinvestment strategy that contains future hedge purchases.
   c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing the scenario reserve volatility across various company must pass the SERT when considering only the 16 economic scenarios, paired with the 100% mortality scenario.

d. The demonstration shall provide an effective evaluation of the residual risk exposure remaining after risk mitigation techniques, such as derivative programs and reinsurance.

2. The company may use one of the following or another method acceptable to the insurance commissioner to demonstrate compliance with subsection Section 7.D.1 above:
   a. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve SR calculated on a stand-alone basis.
   b. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the scenario reserve that results from each of a sufficient number of adverse deterministic scenarios.
   c. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve SR calculated on a stand-alone basis, but using a representative sample of contracts in the stochastic reserve SR calculations.
   d. Demonstrate that any risk characteristics that would otherwise cause the stochastic reserve SR calculated on a stand-alone basis to exceed the statutory reserve calculated in accordance with VM-A and VM-C, are not present or have been substantially eliminated through actions such as hedging, investment strategy, reinsurance or passing the risk on to the contract policyholder by contract provision.
d. The company must disclose a description of contracts and associated features in the certification.

Drafting Note: Consider revisiting Paragraph E.1.e. to possibly either require 1) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario, or 2) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve SR for the group of contracts under the Deterministic Certification Option is determined as follows:

a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).

b. The stochastic reserve SR equals the scenario reserve following the requirements for Section 4.

Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.

Commented [X464]:

Commented [VM22465R464]: Subgroup agrees with including the 100% mortality scenario.

Commented [X466]: It may not be appropriate to use scenario 12 to calculate the scenario reserve for SPIA. See this article https://www.soa.org/sections/financial-reporting/financial-reporting-newsletter/2021/july/fr-2021-07-su/

“In an increasing interest rate environment for business where policyholder behavior is sensitive to prevailing interest rates, life insurers may face an increase in disintermediation risk (i.e., the risk of having to sell assets, potentially at a loss, to fund policyholder surrender benefits) For example, rising interest rates, particularly sudden jumps (e.g., New York 7 pop-up scenario with an immediate interest rate increase of 3 percent), may lead to higher actual and projected policyholder surrenders as policyholders seek out higher yielding investment opportunities. These increasing cash demands may require fixed income assets to be sold at depressed prices, and resultant projected losses (or lower gains) may result in reserve insufficiencies, necessitating the need for AAT reserves.”

Commented [X467]: Recommend deleting guidance note, as it doesn’t provide full or clear scope of what may be excluded, so could be misread to either guarantee option for certain products or exclude the option for other products.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Non-Index Credit Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company only hedges index credits. If the company only hedges index credits from other hedging, then only the section only pertains to the other hedging if the index hedging follows. In those situations, the modeling of hedges supporting index credits can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.A.b.1.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the calculation of the stochastic reserve, determined in accordance with Section 3.D and Section 4.D.

3. The company shall take into account the costs and benefits of hedge positions expected to be held by the company in the future along each scenario. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than 6 months, including the hedging strategy, used to implement the investment policy.

4. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. This also is referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which also is referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

5. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve, otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserveSR otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserveSR needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserveSR attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock-tested.

**Guidance Note:** No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “ Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

**C. Calculation of Stochastic ReserveSR (Reported)**

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no future hedge purchases except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.i.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserveSR is given by:

\[
\text{Stochastic reserveSR} = \text{CTE70 (best efforts)} + E \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}]
\]
4. The company shall specify a value for $E$ (the “error factor”) in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of $E$. The value of $E$ may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, $E$ must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recent available relevant period of data (but no less than 12 months), to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for $E$.

6. Such a back-test shall involve one of the following analyses:

a. For companies that model hedge cash flows directly (“explicit method”), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses – both realized and unrealized – observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g. reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

To support the choice of a low value of $E$, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of $E$ by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an “implicit method” or “cost of reinsurance method”), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

i. Determine the hedge asset gains and losses—both realized and unrealized—incurred over the month attributable to equity, interest rate, and implied volatility movements.

ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).
iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.

iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with less than 6 months of history, E should be at least 1.0.50. However, E may be lower than 1.0.50 if some at least 6 months of reliable experience is available and/or if the change in strategy is a minor refinement rather than a material change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).
8. The company shall set the value of E reflecting the extent to which the future hedging program is defined. To support a value of E below 1.0, there should be very robust documentation outlining the future hedging program. The extent that documentation outlining the future hedging program is incomplete, the value of E shall be increased. Any increases required to the value of E to reflect that documentation is not available to support that the future hedging program is clearly defined shall be in addition to increases to the value of E to reflect a lack of historical experience or to reflect the back-testing results.

E. Additional Considerations for CTE70 (best efforts)

If the company is following a CDHS, the fair value of the portfolio of contracts falling within the scope of these requirements shall be computed and compared to the CTE70 (best efforts) and CTE70 (adjusted). If the CTE70 (best efforts) is below both the fair value and CTE70 (adjusted), the company should be prepared to explain why that result is reasonable.

For the purposes of this analysis, the SR and fair value calculations shall be done without requiring the scenario reserve for any given scenario to be equal to or in excess of the cash surrender value in aggregate for the group of contracts modeled in the projection.

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for purposes of reducing the stochastic reserve SR, the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program.

- The error factor should be temporarily large (e.g., > 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program.

- The error factor should be temporarily 100% for material changes in hedge methodology (e.g., moving from swaps to Treasury futures).

- An increase in the error factor may not always be needed for minor refinements to the hedge strategy (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the new strategy.

An increase in the error factor may not always be needed for minor refinements to the hedge strategy (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the new strategy.

• The error factor should be temporarily 100% for material changes in hedge methodology (e.g., moving from swaps to Treasury futures).

• An increase in the error factor may not always be needed for minor refinements to the hedge strategy (e.g., moving from swaps to Treasury futures).

Commented [X495]: Work is being done by the hedging DG. This is a placeholder. Need to reflect how clearly defined and well documented the hedge program is, to be able to rely on the backtesting provided. To the extent that hedge programs are not clearly defined, E should be increased to reflect that the backtesting cannot be relied on as an indicator of future effectiveness.

Commented [VM22496R495]: Subgroup voted in favor of retaining the fair value disclosure wording here, which is only subject to non-index credit hedges at this point.

Commented [CD497]: This is just too vague to be very useful. It needs to be much more specific, perhaps listing examples of changes that warrant such an increase in E.
on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited to, a hedging strategy where material hedging assets will be obtained when the fixed indexed annuity and other in-scope products account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets. There may be scenarios that are particularly costly to discontinuous hedging strategies, especially where those result in large discontinuous changes in sensitivities (Greeks) associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve $SR$, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve $SR$ otherwise calculated.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the reserves level. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B and Section 12.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may or may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapse, and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more material behavior assumptions, if relevant to the risks in the product, and thus the approach will not underestimate the reserve.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapse, and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more material behavior assumptions, if relevant to the risks in the product, and thus the approach will not underestimate the reserve.

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Account transfers.
- Future deposits.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently (but no less than every 3 years) when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
   b. Surrenders.
   c. Partial withdrawals (systematic and elective).
   d. Account transfers (switching/exchanges).
   e. Resets/ratchets of the guaranteed amounts (automatic and elective).
   f. Future deposits.
   g. Income start date for the benefit utilization.
   h. Commutation of benefit (from periodic payment to lump sum) or vice versa.

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions. For example:
   a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing,) or if the contract provisions incentivize the contract holders to transfer between accounts.
   b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).
   c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

Guidance Note: For some non-elective benefits (nursing home benefits for example), unless relevant company experience exists to the contrary, the use of incidence rates greater than zero after the surrender charge has ended, or the cash value was depleted might be inappropriate may not be prudent since it would reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.
4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):
   a. Gender.
   b. Attained age.
   c. Issue age.
   d. Contract duration.
   e. Time to maturity.
   f. Tax status.
   g. Account value.
   h. Interest credited (current and guaranteed).
   i. Available indices.
   j. Guaranteed benefit amounts.
   k. Surrender charges, transaction fees or other contract charges.
   l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve SR. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100%
efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., the non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holders stochastically modeled.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practicality, allowance for appropriate simplifications, approximations and modeling efficiency techniques, the use of dynamic models is encouraged, but not mandatory. Static assumptions risk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers), may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of behavior consistent with the economic scenarios and other variables in the model, including the non-scenario tested assumptions. The company shall test the sensitivity of results to understand the materiality of making alternate assumptions and follow the guidance discussed above on setting assumptions for sensitive behaviors.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution). To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the model) in order to determine exactly which scenario results are included in the CTE measure. Rather, in light of the products being valued, the company should be mindful of the general characteristics of those scenarios likely to represent the tail of the loss distribution and consequently use prudent estimate assumptions for behavior that are reasonable and appropriate in such scenarios. For non-variable annuities, these “valuation” scenarios would typically display one or more of the following attributes:
   a. Declining, increasing and/or volatile index values, where applicable.
   b. Price gaps and/or liquidity constraints.
   c. Rapidly changing interest rates or persistently low interest rates.
   d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions.
a. Remain logically and internally consistent across the scenarios tested.

b. Represent plausible outcomes.

c. Lead to appropriate, but not excessive, asset requirements.

4. The company should remember that the continuum of “plausibility” should not be confined or constrained to the outcomes and events exhibited by historic experience.

5. Companies should attempt to track experience for all assumptions that materially affect their risk profiles by collecting and maintaining the data required to conduct credible and meaningful studies of contract holder behavior.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse benefit may have relevance to the early durations of contracts with living benefits) and relevant to experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:

   a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.

   b. Complies with the contract holder behavior requirements stated in Section 10.A to Section 10.G above in this section.

2. If the company models policy loans explicitly, the company shall:

   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.

   b. Assign loan balances either to exactly match each policy's contract's utilization or to reflect average utilization over a model segment or sub-segments if the results are materially similar.

   c. Model policy loan interest in a manner consistent with policy's contract provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
5. The company may exclude any portion of an NGE that:
d. Model policy loan principal repayments, including those that occur automatically upon death or surrender. Include policy loan principal repayments as a positive policy loan cash flow, per Section 4.A.1.h.
e. Model additional policy loan principal. Include additional policy loan principal as a negative policy loan cash flow, per Section 4.A.1.h (but do not include interest added to the loan balance as a negative policy loan cash flow).
f. Model any investment expenses allocated to policy loans and include them either with negative policy loan cash flows or insurance expense cash flows.

I. Non-Guaranteed Elements
Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy contract costs or values and are not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to non-variable annuities include but are not limited to the following: fixed credited rates on fixed accounts, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollover rates, rollover period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.J.I.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of an NGE that:
   a. Is not based on some aspect of the policy’s or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude...
from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.

   a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve SR.

   b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve SR should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the Stochastic Reserve. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.)

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from similar industries or geographies that may be used to sub-divide in-force blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to
how payout annuities vs. deferred annuities are distinguished.

Guidance Note: Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.

4. Margin for Data Uncertainty

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) mortality (longevity) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a mortality (longevity) plus (minus) segment to a longevity (mortality) minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2; for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

Commented [X597]: Comment on note for reinsurance riders, it would be easier to understand the mortality (longevity) segments.

Commented [VM22594R593]: It may be necessary to reclassify a business segment from a plus (minus) segment to a minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

Commented [VM22596R595]: This comment will be reflected in next exposure.
i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:

\[ q_x^{20XX+n} = q_x^{20XX}(1 - G_{2,x})^n \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage (F_x) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual deferred annuities and deferred annuity contracts with guaranteed living benefits

\[ q_x^{2012+n} = q_x^{2012}(1 - G_{2,x} - F_x) \]

b. [1983 Table “a”] for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuitants

\[ q_x^{1994+n} = q_x^{1994}(1 - A_{AA})^n \]

#### Additional Considerations Involving Data

### Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

### Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by...
contract duration for an appropriate select period. As an alternative, if the company determines that mortality is affected by selection, the company could apply margins to the expected mortality in such a way that the actual mortality modeled does not depend on contract duration.

c. Modification and Relevance of Data

Even for a large company, the quantity of life exposures and deaths are such that a significant amount of smoothing may be required to determine expected mortality curves from mortality experience. Expected mortality curves, when applied to the recent historic exposures (e.g., three to seven years), should not result in an estimate of aggregate number of deaths less (greater) than the actual number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying data), older data may no longer be relevant. The “age” of the experience data used to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors that include, but are not limited to, trends in mortality experience, trends in exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative to mortality by amounts, changes in the mix of business and product features that could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves including margins for uncertainty with the mortality assumptions described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

Guidance Note: For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the industry mortality assumption described in Section 11.B.3 used in the blending.

2. Adjustment of Statutory Valuation Industry Mortality for Improvement

For purposes of the adjustment for credibility, the industry mortality table for a plus segment may be and the industry mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective industry mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.
b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.

f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve $SR$. If such an adjustment would reduce the stochastic reserve $SR$, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Other Guidance and Requirements for Assumptions

A. Overview

This section provides guidance and requirements in general for setting prudent estimate assumptions when determining either the SR or DR. It also provides specific guidance and requirements for expense assumptions.

B. General Assumption Requirements

1. The company shall use prudent estimate assumptions for risk factors that are not stochastically modeled by applying margins to the anticipated experience assumptions if such risk factors have been categorized as material risks by following Section 1.B Principle 3 and requirements in Section 12.C.

2. The company shall establish the prudent estimate assumptions for risk factors in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

3. The company shall model the following risk factors stochastically unless the company elects the stochastic modeling exclusion defined in Section 7:

   a. Interest rate movements (i.e., Treasury interest rate curves).
   b. Equity performance (e.g., Standard & Poor’s 500 index [S&P 500] returns and returns of other equity investments).

4. If the company elects to stochastically model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.

   Guidance Note: It is expected that companies will not stochastically model risk factors other than the economic scenarios, such as contract holder behavior or mortality, until VM-22 has more specific guidance and requirements available. Companies shall discuss with domiciliary regulators if they wish to stochastically model other risk factors.

5. The company shall use its own experience, if relevant and credible, to establish an anticipated experience assumption for any risk factor. To the extent that company experience is not available or credible, the company may use industry experience or other data to establish the anticipated experience assumption, making modifications as needed to reflect the circumstances of the company.

   a. For risk factors (such as mortality) to which statistical credibility theory may be appropriately applied, the company shall establish anticipated experience assumptions for the risk factor by combining relevant company experience with industry experience data, tables or other applicable data in a manner that is consistent with credibility theory and accepted actuarial practice.
b. For risk factors (such as utilization of guaranteed living benefits) that do not lend themselves to the use of statistical credibility theory, and for risk factors (such as some of the lapse assumptions) to which statistical credibility theory can be appropriately applied but cannot currently be applied due to lack of industry data, the company shall establish anticipated experience assumptions in a manner that is consistent with accepted actuarial practice and that reflects any available relevant company experience, any available relevant industry experience, or any other experience data that are available and relevant. Such techniques include:

i. Adopting standard assumptions published by professional, industry or regulatory organizations to the extent they reflect any available relevant company experience or reasonable expectations.

ii. Applying factors to relevant industry experience tables or other relevant data to reflect any available relevant company experience and differences in expected experience from that underlying the base tables or data due to differences between the risk characteristics of the company experience and the risk characteristics of the experience underlying the base tables or data.

iii. Blending any available relevant company experience with any available relevant industry experience and/or other applicable data using weightings established in a manner that is consistent with accepted actuarial practice and that reflects the risk characteristics of the underlying contracts and/or company practices.

c. For risk factors that have limited or no experience or other applicable data to draw upon, the assumptions shall be established using sound actuarial judgment and the most relevant data available, if such data exists.

d. For any assumption that is set in accordance with the requirements of Section 12.B.5.c, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing and disclose the analysis performed to ensure that the assumption is set at the conservative end of the plausible range.

e. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

6. The company shall sensitivity test risk factors that are not stochastically modeled and examine the impact on the stochastic reserve. The company shall update the sensitivity tests periodically as appropriate. The company may update the tests less frequently, but no less than every 3 years, when the tests show less sensitivity of the stochastic reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company...
may perform sensitivity testing:

a. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.

b. Using data from prior periods.

Guidance Note: Sensitivity testing every risk factor on an annual basis is not required. For some risk factors, it may be reasonable, in lieu of sensitivity testing, to employ statistical measures for margins, such as adding one or more standard deviations to the anticipated experience assumption.

7. The company shall vary the prudent estimate assumptions from scenario to scenario within the stochastic reserve calculation in an appropriate manner to reflect the scenario-dependent risks.

C. Assumption Margins

The company shall include margins to provide for adverse deviations and estimation error in the prudent estimate assumption for each risk factor that is not stochastically modeled or prescribed, subject to the following:

1. The level of margin applied to the anticipated experience assumptions may be determined in aggregate or independently as discussed in Section 1.B Principle 3.

Risks that are stochastically modeled (e.g., interest rates, equity returns) or have prescribed margins or guardrails (e.g., assets, revenue sharing) shall be considered material risks. Other risks generally considered to be material include, but are not limited to, mortality, contract holder behavior, maintenance and overhead expenses, inflation and implied volatility. In some cases, the list of material risks may also include acquisition expenses, partial withdrawals, policy loans, annuitizations, account transfers and deposits, and/or option elections that contain an element of anti-selection.

2. The greater the uncertainty in the anticipated experience assumption, the larger the required margin, with the margin added or subtracted as needed to produce a larger Sr or DR than would otherwise result. For example, the company shall use a larger margin when:

   a. The experience data have less relevance or lower credibility.
   b. The experience data are of lower quality, such as incomplete, internally inconsistent or not current.
   c. There is doubt about the reliability of the anticipated experience assumption, such as, but not limited to, recent changes in circumstances or changes in company policies.
   d. There are constraints in the modeling that limit an effective reflection of the risk factor.
3. In complying with the sensitivity testing requirements in Section 12.B.6 above, greater analysis and more detailed justification are needed to determine the level of uncertainty when establishing margins for risk factors that produce greater sensitivity on the stochastic reserve.

4. A margin is permitted but not required for assumptions that do not represent material risks.

5. A margin should reflect the magnitude of fluctuations in historical experience of the company for the risk factor, as appropriate.

6. The company shall apply the method used to determine the margin consistently on each valuation date but is permitted to change the method from the prior year if the rationale for the change and the impact on the stochastic reserve is disclosed.

D. Expense Assumptions

1. General Prudent Estimate Expense Assumption Requirements

In determining prudent estimate expense assumptions, the company:

a. May spread certain information technology development costs and other capital expenditures over a reasonable number of years in accordance with accepted statutory accounting principles as defined in the Statements of Statutory Accounting Principles.

Guidance Note: Care should be taken with regard to the potential interaction with the inflation assumption below.

b. Shall assume that the company is a going concern.

c. Shall choose an appropriate expense basis that properly aligns the actual expense to the assumption. If values are not significant, they may be aggregated into a different base assumption.

Guidance Note: For example, death benefit expenses should be modeled with an expense assumption that is per death incurred.

d. Shall reflect the impact of inflation.

e. Shall not assume future expense improvements.

f. Shall not include assumptions for federal income taxes (and expenses paid to provide fraternal benefits in lieu of federal income taxes) and foreign income taxes.

g. Shall use assumptions that are consistent with other related assumptions.

h. Shall use fully allocated expenses.

Guidance Note: Expense assumptions should reflect the direct costs associated with the block of contracts being modeled, as well as indirect costs and overhead costs that have been allocated to the modeled contracts.

i. Shall allocate expenses using an allocation method that is consistent across
company lines of business. Such allocation must be determined in a manner that is within the range of actuarial practice and methodology and consistent with applicable ASOPs. Allocations may not be done for the purpose of decreasing the stochastic reserve.

i. Shall reflect expense efficiencies that are derived and realized from the combination of blocks of business due to a business acquisition or merger in the expense assumption only when any future costs associated with achieving the efficiencies are also recognized.

Guidance Note: For example, the combining of two similar blocks of business on the same administrative system may yield some expense savings on a per unit basis, but any future cost of the system conversion should also be considered in the final assumption. If all costs for the conversion are in the past, then there would be no future expenses to reflect in the valuation.

k. Shall reflect the direct costs associated with the contracts being modeled, as well as an appropriate portion of indirect costs and overhead (i.e., expense assumptions representing fully allocated expenses should be used), including expenses categorized in the annual statement as “taxes, licenses and fees” (Exhibit 3 of the annual statement) in the expense assumption.

l. Shall include acquisition expenses associated with business in force as of the valuation date and significant non-recurring expenses expected to be incurred after the valuation date in the expense assumption.

m. For contracts sold under a new policy form or due to entry into a new product line, the company shall use expense factors that are consistent with the expense factors used to determine anticipated experience assumptions for contracts from an existing block of mature contracts taking into account:

i. Any differences in the expected long-term expense levels between the block of new contacts and the block of mature contracts;

ii. That all expenses must be fully allocated as required under Section 12.D.1.h above.

2. Margins for Prudent Estimate Expense Assumptions

The company shall determine margins for expense assumptions following Section 12.C.
Section 13: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The allocation shall be made separately for DR and SR. The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

Table 12.1: Sample Allocation of Aggregate Reserve

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td></td>
<td>140</td>
</tr>
<tr>
<td>Allocation Basis for the excess of the Aggregate Reserve over the Cash Surrender Value</td>
<td>10</td>
<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

### Option 2: Actuarial Present Value Approach

B. The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve defined in Section 3.D.
   
   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows, as well as any cash flows that are scenario dependent.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.
   
   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve defined in Section 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

<table>
<thead>
<tr>
<th>Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value</th>
<th>Li = (Ai)/ΣA*[Aggregate Reserve - ΣCi]</th>
<th>9.09</th>
<th>10.91</th>
<th>0.00</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contract-level reserve Ci+ Li</td>
<td>37.09</td>
<td>50.91</td>
<td>52.00</td>
<td>140.00</td>
<td></td>
</tr>
</tbody>
</table>

Commented [X637]: This method depends on the NAER, so would not work for companies that use direct iteration.

Commented [X638]: This could give an unstable allocation if there is an even mix of products with different risk profiles, so that the tail is populated with some scenarios where Product A does poorly and some where Product B does poorly. The single scenario will only reflect the riskiness of one of the products.

Commented [X639]: Not just the NAER, but the cashflows are also scenario dependent.

Commented [VM22640R639]: Edits to address this comment will be reflected in next exposure.

Commented [CD641]: Section 3.D

Commented [VM22642R641]: Edits to address this comment will be reflected in next exposure.

</table>

*Cash Surrender Value  
**Guaranteed Lifetime Withdrawal Benefit

**Guidance Note:** The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 1314: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section and all contracts not passing the SET covered by Sections 1 through 13 of VM-22, are covered Section 14 of VM-22:

   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

Guidance Note: For Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f and Section 1314.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:

   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f, Section 1314.A.2.g or Section 1314.A.2.h, the
company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 4.4.14 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B) (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C) (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   Guidance Note: Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   Guidance Note: The determination in Section 4.4.14.B.1.c above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   Guidance Note: If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.
3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.

4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her age last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 1314 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)†

   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.

   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

   Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5 Years</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>90+</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>80–89</td>
<td>B</td>
<td>C</td>
<td>D</td>
<td></td>
</tr>
<tr>
<td>70–79</td>
<td>C</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>&lt; 70</td>
<td>D</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

2. Premium Determination Dates

a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d</td>
<td>Fixed payout annuities resulting from settlement options or annuitizations from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.e</td>
<td>Fixed income payment streams from CDAs, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
<tr>
<td>A.2.g</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
Guidance Note: For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

b. Immaterial Change in Consideration

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

3. Statutory Maximum Valuation Interest Rate

a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 1314.C.1) and its Premium Determination Date (Section 1314.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

d. Quarterly Valuation Rate:

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ I_q = R + S - D - E \]

Where:

a. \( R \) is the reference rate for that Valuation Rate Bucket (defined in Section 1314.C.4);

b. \( S \) is the spread rate for that Valuation Rate Bucket (defined in Section 1314.C.5);

c. \( D \) is the default cost rate for that Valuation Rate Bucket (defined in Section 1314.C.6);
and

d.  $E$ is the spread deduction defined as 0.25%.

c.  **Daily Valuation Rate:**

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

$$I_d = I_q + C_{d-1} - C_q$$

Where:

a.  $I_q$ is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b.  $C_{d-1}$ is the daily corporate rate (defined in Section 1314.C.7) for the business day immediately preceding the premium determination date; and

c.  $C_q$ is the average daily corporate rate (defined in Section 1314.C.8) corresponding to the same period used to develop $I_q$.

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate ($I_d$) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4.  **Reference Rate**

Reference rates are updated quarterly as described below:

a.  The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from [https://fred.stlouisfed.org](https://fred.stlouisfed.org), and is rounded to two decimal places.

b.  Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c.  The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

5.  **Spread**

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a.  Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b.  Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.1) effective for the calendar year in which the premium determination date falls.

6.  **Default costs for each Valuation Rate Bucket** are updated annually as described below:

a.  Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: [https://research.stlouisfed.org/fred2/categories/32348](https://research.stlouisfed.org/fred2/categories/32348). To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: [https://research.stlouisfed.org/fred2/series/[replace with series name from the table below]].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAML1C1A0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAML2C2A0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAML3C3A0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAML4C4A0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAML7C7A0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAML8A0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: [https://research.stlouisfed.org/fred2/categories/32348](https://research.stlouisfed.org/fred2/categories/32348). To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: [https://research.stlouisfed.org/fred2/series/[replace with series name from Section 1314.C.7.a]].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating Iq in Section 1314.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:

i. Bucket A:
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   b) Five-year certain only.

ii. Bucket B:
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   b) 10-year certain only.

iii. Bucket C:
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   c) 15-year certain only.

iv. Bucket D:
   a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
   b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for
individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

   a) Column 1 of Table 4 is identical to column 1 of Table 1.
   b) Column 2 of Table 4 is 50% of column 2 of Table 1.
   c) Column 3 of Table 4 is identical to column 2 of Table 4.
   d) Column 4 of Table 4 is 50% of column 3 of Table 1.
   e) Column 5 of Table 4 is identical to column 4 of Table 4.
   f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 1314.A.2.i), the following apply:

a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

Guidance Note: Under some group annuity contracts, certificates may be purchased on different
In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

**Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.
Valuation Manual Section II] Reserve Requirements

Subsection 2: Annuity Products

A. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

B. Minimum reserve requirements for non-variable annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 13 of VM-22:

1. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.

2. Credits a rate of interest under the contract prior to the application of any market value adjustments that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

D. Minimum reserve requirements are defined as those requirements as found in Sections 1 through 13 of VM-22, Statutory Maximum Valuation Interest Rates for Income Annuity Formulas.

E. Index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for assessing whether VM-21 or VM-22 requirements apply:

1. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.

2. Credits a rate of interest under the contract prior to the application of any market value adjustments that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.
F. Index-linked or modified guaranteed annuity contracts or riders that do not satisfy either of the two conditions listed above criteria in Paragraph Section 2.E.1 or Section 2.E.2 above and E.1. It may be a key consideration for application of VM-21 are issued on 1/1/2024 and later are those requirements as found in VM-21.

Commented [X661]: VM-21 specifically says “These requirements do not apply to contracts falling under the scope of VM-A-255: Modified Guaranteed Annuities; however, they do apply to contracts listed above that include one or more subaccounts containing features similar in nature to those contained in modified guaranteed annuities (MGAs) (e.g., market value adjustments).” Is this a contradiction?

Commented [X662]: Consistent with E above.

Commented [VM2263R662]: Edits to address this comment will be reflected in next exposure.
Guidance Note: Designs of policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraphs A through C above, including, but not limited to, Guaranteed Minimum Death Benefits, Guaranteed Minimum Income Benefits, Guaranteed Minimum Withdrawal Benefits, Guaranteed Lifetime Income Benefits, Guaranteed Lifetime Withdrawal Benefits, Guaranteed Payout Annuity Floors, Waiver of Surrender Charges, Return of Premium, Systematic Withdrawal Benefits under Required Minimum Distributions, and all similar guaranteed benefits shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.

2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.

3. After issuance, the base policy or contract value or benefits are determined by referencing the base policy or contract features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

E. If a term life insurance rider on the named insured(s) on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is
separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.

G.F. For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

H.G. Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve (for VM-20 and VM-22) or TAR (for VM-21) if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves (for VM-20 and VM-22) or reserves and TAR (for VM-21) using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.
Proposed revision is not appropriate. Item (a) is unnecessary, and items under (b) would be addressed via simplifications and thus are indirectly reflected. Recommend deleting the whole section 1.C.3 including item (a) and item (b).

The revised language “sudden and significant levels of withdrawal and surrenders” replaces the original language “run on the bank” and is less clear. Does “significant” mean severe or extreme? Or just appreciably? Withdraws and surrenders certainly may vary by projected economic scenarios. Recommend using the original language “run on the bank” that had a clearer intent.

We recommend deleting the wording “fundamentally”. If a breakthrough is known to have fundamentally changed expected future mortality, but is not yet significantly reflected in historical experience, why is it not reflected? Do we know about this fundamental shift for years before it is reflected? This issue also applies to the VM-21 requirement.

We recommend removing the bullet “Significant future reserve increases as an unfavorable scenario is realized” as this is extraneous.

The term Buffer Annuity is not interchangeable to Registered Index-Linked Annuity (RILA) since Buffer Annuity is a subset of RILA. RILA can have different downside protections such as "Buffer" or "Floor". Recommend deleting Buffer Annuity or add descriptions for Buffer Annuity as a subtype in the RILA definition.

Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

The definition of FIA describes the account value as typically with guaranteed principal. Since FIA always has the guaranteed principal, recommend deleting the wording “typically”.

It is unclear to us why RILA is defined in VM-22 when it is being used to exclude the product from VM-22 requirements.

ACLI already following up on a proposal to address the scope and definitions, which will address this issue.

Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

© 2022 National Association of Insurance Commissioners
This sub-section seems more appropriate in Section 4 (or pulled out completely and consolidated within "I. Introduction" or "VM-01" and applied to all PBR methods).

VM-21 Section 3.H on simplifications, approximations, and modeling efficiency techniques is missing (including the Guidance Note). Would it make sense to add it?

Edits to address this comment will be reflected in next exposure

Recommend to periodically review at least every three years.

Should this be "the company... shall", rather than the "qualified actuary... shall"? Not sure why this particular task falls on the QA, when "the company" generally has responsibility for PBR and, in the subsection directly before this one, the company is assigned the task of establishing prudent estimate assumptions.

Edits to address this comment will be reflected in next exposure

Suggest replacing “If the results of statistical testing or other testing” with “If the results of the review” to simplify language and avoid possible confusion.

Edits to address this comment will be reflected in next exposure

Recommend replacing “the qualified actuary” with “the Company” consistent with general PBR requirements that the company set assumptions.

Edits to address this comment will be reflected in next exposure

should this be “the company”? See prior comment.

Edits to address this comment will be reflected in next exposure
New language drafted by select Subgroup Members to provide certain conditions under which SPIA contracts could automatically pass the exclusion test.

Suggest renaming this section header/name to "Requirements to Pass the SET". There is only 1 SET, but 3 ways to pass it (SERT, Demonstration or Certifications). The language gets confusing (here and elsewhere) when you start saying there are different "types" of SETs.

We recommend removing "pension risk transfer business" from products scoped out of SET certification method. It is unclear why this business would be treated differently from individually issued business for testing intended to capture interest rate risk.

Subgroup voted to keep PRT ineligible for the Certification Method.

See earlier comments about the use of “future”

Edits to address this comment will be reflected in next exposure.

what is meant by "aggregate risk levels"? Aggregated across what? Need clarification on the intentions for adding this phrase, when it is not in VM-20. Otherwise, i would suggest deleting this.

Edits to address this comment will be reflected in next exposure.

This is not in VM-20 and would substantially change the exclusion. The intent is not to allow you to group a block that has material interest rate risk with a larger block that is insensitive to interest rate risks and thereby pass. If "aggregate" referred to potential compounding of interest rate, longevity, or asset risk then this could be redrafted to clearly call out a 4th category of risk due to a combination of the first three. However, I think this is already implicitly covered.

note, there is no insertion of "aggregate risk levels across" here, like there was above. (to be clear, i don't support adding it.)

Page 35: [85] Commented [CD380] CA DOI 12/30/2021 4:16:00 PM
This wording is a little clunky here. My suggestion:
"A demonstration that, for the group of contracts, reserves calculated using requirements under VM-A and VM-C are at least as great..."

Need to add a review of the company's mortality and/or longevity risk.

Edits to address this comment will be reflected in next exposure

Page 35: [94] Commented [X393] ACLI
As written, the SERT assumes a single premium product given the change of the denominator to the scenario reserve. Alternative product designs (such as longevity swap) could result in unintended results. We recommend maintaining consistency with VM-20 and using a denominator of future benefits (annuity payments, DBs, etc., excluding premium considerations, expenses, etc.).
Consensus to use a denominator that only includes benefits and expenses, consistent with VM-20

Using (a) in the denominator instead of VM-20's (c) which is a PV of benefits could make this ratio unstable when the scenario reserve (a) is very small. This is particularly applicable if the block being tested does not have CSV.

Consensus to use a denominator that only includes benefits and expenses, consistent with VM-20

The variability should be assured to be immaterial based on the company's materiality standard.
The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met June 29, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Mike Yanacheak (IA); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Mike Boerner and Yujie Huang (TX); and Craig Chupp (VA).

1. **Reviewed the Updated VM-22 Subgroup Documents**

   Mr. Slutsker said the drafting discussion log (Attachment Twenty-One-A) has been updated to include the tier three comments. He presented an updated version of the proposed VM-22 framework (Attachment Twenty-One-B), which reflects the tier one and tier two comments that have been addressed.

2. **Discussed the Allocation of Excess Reserves**

   Mr. Slutsker said that two options have been proposed for the allocation of the excess of reserves over cash values. He said the first option allocates the excess in the same manner as VM-21, Requirements for Principle-Based Reserves for Variable Annuities, which uses the measure of the risk of the product relative to its cash surrender value. He said the second option uses the excess of the present value of the projected liability cash flows to allocate the excess reserves. Brian Bayerle (American Council of Life Insurers—ACLI) said the ACLI wants to ensure that the method chosen is consistent with other requirements. He said they are testing the options and will share the outcome of the testing once it is completed. He said they are particularly concerned with non-life contingent contracts. Chris Conrad (American Academy of Actuaries—Academy) said both options will be considered as part of the VM-22 field test. Mr. Slutsker said the allocation method decision will be deferred until after the field test.

3. **Discussed Working Reserve for Contracts with no Cash Surrender Value**

   Mr. Slutsker said there is a question of whether to set a working reserve floor for contracts that have no cash surrender value. Al Zlogar (Academy) said it is unlikely that a model segment would combine contracts with cash surrender values and contracts with no cash surrender values because of the aggregation rules, which require the separation of the payout and accumulation categories. He said the Academy will work on a definition for a working reserve or working cash surrender value.

4. **Discussed Reserve Categorization Upon Depletion of Fund Value**

   Mr. Slutsker asked how the proposed VM-22 framework should categorize accumulation contracts after their fund values have been depleted. Mr. Zlogar said that the Academy prefers a principle-based approach, which allows the company management of the investments supporting the liabilities to determine the categorization of the contract for reserving purposes. He said that in most cases, the assets are transferred to the payout reserving category. He noted that generally accepted accounting principles (GAAP) require that the reserves move from market risk benefit reserves to liability for future policy benefit reserves. He said one would expect the asset categorization to follow the categorization of the GAAP reserves. Mr. Slutsker asked how companies with no single premium immediate annuities or deferred income annuities would address their deferred annuities when the funds are depleted and the contract begins paying out guaranteed living benefits. John Miller (Academy) said the working reserve concept could come into play in that situation. Mr. Slutsker asked if forcing the contracts with...
depleted fund values into the payout reserving category would alleviate the need to address the working reserve issue. Mr. Zlogar said that it is unclear whether that will be the case. Mr. Slutsker said that for the initial exposure, the contracts with depleted funds will be required to move to the payout reserving category. He said comments can be submitted at that time. Cindy Barnard (Pacific Life) said that treatment is inconsistent with VM-21. Mr. Slutsker said a drafting note will be added to solicit feedback on the consistency with VM-21.

5. Review Tier Three Comments in the VM-22 draft

Mr. Bayerle said that in Section I of the proposed VM-22 framework, the guidance note that references C-3 Phase II should be retained to acknowledge that a link to risk-based capital (RBC) will continue to exist. He said the appropriate wording can be added later. Mr. Slutsker suggested working offline with Mr. Bayerle to develop proposed wording.

Mr. Slutsker said the California Department of Insurance (DOI) commented that the VM-22 principles should align with VM-21. He said when the VM-22 framework proposal is completed, a document that outlines the differences from VM-21 will be produced. He said differences can be discussed at that time.

Mr. Bayerle said principle #2 is contradicted in later sections of the proposed VM-22 framework. He suggested revising the principle to reflect recent changes. Mr. Slutsker said the issue can be addressed when considering the language for the RBC guidance note.

Mr. Slutsker said that the TDI suggested reinstating the guidance note that gives examples where full aggregation may not be possible under principle #2. There were no objections to reinstating the guidance note.

Having no further business, the VM-22 (A) Subgroup adjourned.

Section 1: Background

A. Purpose

Sections 1 through 13 of these requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2018. Section 14 of these requirements establish the maximum valuation rate for payout annuities for contracts issued on or after 1/1/2018. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts and certificates, the Commissioners Reserve Valuation Method (CRVM).

Guidance Note: CRVM requirements apply to some group pension contracts.

B. Principles

The projection methodology used to calculate the stochastic reserveSR is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves.

Guidance Note: The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

Principle 1: The objective of the approach used to determine the stochastic reserveSR is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

Principle 2: The calculation of the stochastic reserveSR is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cashflow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserveSR at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

Guidance Note: Examples where full aggregation between contracts may not be possible include experience rated group contracts and the operation of reinsurance treaties.

Principle 3: The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the...
company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the stochastic reserve \( SR \) at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve \( SR \), the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

**Guidance Note:** The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle. More guidance and requirements for setting assumptions in general are provided in Section 12.

**Principle 4:** While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve \( SR \) is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

**Principle 5:** Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve \( SR \). Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve \( SR \) without also reducing risk on scenarios similar to those used in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

### C. Risks Reflected

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and
   b. Capable of materially affecting the reserve.

**Commented [X17]:** We suggest deleting the sentence "Generally, assumptions are..." since it does not provide guidance. We also suggest tightening the remainder of the text for clarity.

**Commented [X18]:**

**Commented [VM2219R18]:** Subgroup agreed with this comment. Edits to address this comment will be reflected in next exposure.

**Commented [X20]:** Principle 5 has the statement "nor a method based on factors calibrated to the results of a cash-flow scenario model" which is intended for the Alternative Methodology in VM-21. The statement should be deleted from VM-22.

**Commented [VM2219R20]:** Edits to address this comment will be reflected in next exposure.

**Commented [X22]:** We recommend deleting the third sentence (starting with "Therefore, the use of assumptions...") because this lacks historical context and is covered by the final sentence.

**Commented [X23]:**

**Commented [VM2224R23]:** The Subgroup is open to a common chapter with all risks identified for different PBR frameworks, but decided to hold off on developing for now.

**Commented [CD25]:** VM-21 has "... and Risks Not Reflected" in this section header, which should be retained here since the section on risks not reflected is still in here.
2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:

a. Asset risks
   i. Credit risks (e.g., default or rating downgrades).
   ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).
   iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).
   iv. Performance of equities, real estate, and Schedule BA assets.
   v. Call risk on callable assets.
   vi. Separate account fund performance.
   vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).
   viii. Currency risk.

b. Liability risks
   i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.
   ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.
   iii. Utilization risk associated with guaranteed living benefits.
   iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.
   v. Annuityization risks.
   vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).
   vii. Applicable expense risks, including fluctuation in maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks
   i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.
   ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).
iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:
   a. Those not associated with the policies or contracts being valued, or their supporting assets.
   b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
      i. Liquidity risks associated with a sudden and significant levels of withdrawals and surrenders. 
         "run on the bank.
   b. Liability risks
      i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.
      ii. Catastrophic events (e.g., epidemics or terrorist events).
      iii. Major breakthroughs in life extension technology that have not yet fundamentally-altered recently observed mortality experience.
      iv. Significant future reserve increases as an unfavorable scenario is realized.
   c. General business risks
      i. Deterioration of reputation.
      ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.
      iii. Poor management performance.
      iv. The expense risks associated with fluctuating amounts of new business.
      v. Risks associated with future economic viability of the company.
      vi. Moral hazards.
      vii. Fraud and theft.
      viii. Operational.
      ix. Litigation.
D. Specific Definitions for VM-22

**Buffer Annuity:**
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

- **Deferred Income Annuity (DIA):**
  An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin up to 13 months or later after (or from) the issue date if the contract holder survives to a predetermined future age.

- **Fixed Indexed Annuity (FIA):**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, subject to certain limits, typically with guaranteed principal.

- **Flexible Premium Deferred Annuity (FPDA):**
  An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

- **Funding Agreement:**
  A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

- **Guaranteed Investment Contract (GIC):**
  An insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

- **Index Credit Hedge Margin:**
  A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

- **Index Credit:**
  Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to contract policy values that is linked to an index or indices. Amounts credited to the contract policy resulting from a floor on an index account are included.
• **Index Crediting Strategy**
  The strategy defined in a contract to determine index credits for a contract. This refers to underlying index, index parameters, date, timing, performance triggers, and other elements of the crediting method.

• **Index Parameter**
  Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

• **Longevity Reinsurance**
  An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

  Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

  Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

• **Market Value Adjustment (MVA) Annuity**
  An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

• **Modified Guaranteed Annuity (MGA)**
  A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values and death benefits that are based upon a market-value adjustment formula if held for shorter periods.

---

Commented [X67]: We would suggest adding performance triggers to the list, along with other potential crediting methods; alternatively, the definition could specify that the crediting methods listed are examples only.

Commented [VM2268R67]: Edits to address this comment will be reflected in next exposure.

Commented [X69]: The definition assumes that longevity swaps are not included in this definition. Why is this the case? Doesn’t this imply that longevity swaps are not within the scope of the definition of “A Scope” if that is the case? Clarification would be helpful on what guidance should be used for these contracts.

Commented [VM2270R69]: Academy will follow-up with proposed revisions to the definition of Longevity Reinsurance.

Commented [VM2271]: Longevity reinsurance may generate longevity index-based longevity swaps.

Commented [VM2272R71]: VM-22 subgroup has exposed a proposal from NJ to address this issue.

Commented [X73]: We recommend editing the definition as follows: “A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account.”

Commented [VM2274R73]: Edits to address this comment will be reflected in next exposure.

Commented [X75]: To clarify definition of MGA, recommend adding “death benefits.”

Commented [VM2276R75]: Edits to address this comment will be reflected in next exposure.
**Multi-Year Guaranteed Annuity (MYGA)**
A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

**Pension Risk Transfer (PRT) Annuity**
An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

**Registered Index-Linked Annuity (RILA)**
A contract that provides periodic benefits and is purchased with a single premium amount. The contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

**Single Premium Immediate Annuity (SPIA)**
An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within 13 months one year after (or from) the immediate issue date.

**Single Premium Deferred Annuity (SPDA)**
An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.

**Stable Value Contract**
A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

**Structured Settlement Contract (SSC)**
A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

**Synthetic Guaranteed Investment Contract (Synthetic GIC)**

---

**Commented [CD77]:** Should this be “Multi-Year” instead of “Multiple Year”? The former is the more commonly used term for MYGA.

**Commented [VM2278R77]:** Suggest replacing “fixed annuity” with “variable annuity” in the second sentence of the definition of RILA.

**Commented [CD80]:** Suggest rephrasing “burden” to “exposure.”

**Commented [VM2281R80]:** Suggest replacing “current” with “expected” in the definition of RILA.

**Commented [CD79]:** “fixed annuity” is not defined. It is better to change all instances of “fixed annuity” to “non-variable annuity” to be consistent with the terminology introduced in Section 1A (and to be aligned with the actual VM-22 chapter name)? An alternative could be to add a definition for “fixed annuity”, with the definition of it being a “non-variable annuity.”

**Commented [CD80]:** Suggest replacing “burden” to “exposure.”

**Commented [VM2284R83]:** If a contract is recognized this way, it will be more transparent for the contract holder. Suggest including some kind of “Fixed Indexing” feature in the definition of RILA.

**Commented [CD79]:** “fixed annuity” is not defined. It is better to change all instances of “fixed annuity” to “non-variable annuity” to be consistent with the terminology introduced in Section 1A (and to be aligned with the actual VM-22 chapter name)? An alternative could be to add a definition for “fixed annuity”, with the definition of it being a “non-variable annuity.”

**Commented [CD80]:** Suggest replacing “burden” to “exposure.”
Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the contract holder or plan trust.

- **Term Certain Payout Annuity**
  A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

- **Two-Tiered Annuity**
  A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.

The term “cash surrender value” means, for the purposes of these requirements, the amount available to the contract holder upon surrender of the contract. Generally, it is equal to the account value less any applicable surrender charges, where the surrender charge reflects the availability of any free partial surrender options. However, for contracts where all or a portion of the amount available to the contract holder upon surrender is subject to a market value adjustment, the cash surrender value shall reflect the market value adjustment consistent with the required treatment of the underlying assets. That is, the cash surrender value shall reflect any market value adjustments where the underlying assets are reported at book value.

The term “guaranteed minimum death benefit” (GMDB) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount; or (ii) exceeds the minimum amount and is:

- increased by an amount that may be either specified by or computed from other policy or contract values; and
- has the potential to produce a contractual total amount payable on such death that exceeds the account value; or
- in the case of an annuity providing income payments, guarantees payment upon such death of an amount payable on death in addition to the continuation of any guaranteed income payments.

E. **Materiality**

The company shall establish a standard containing the criteria for determining whether an assumption, risk factor, or other element of the principle-based valuation has a material impact on the size of the reserve. This standard shall be applied when identifying material risks.

Section 2: Scope and Effective Date
A. Scope

Subject to the requirements of this Sections 1 to 13 of VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below:

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

Products in scope of VM-22 include non-variable based annuities which consist of, but are not limited to, the following list:

- **Account Value Based Annuities**
  1. Deferred Annuities (SPDA & FPDA)
  2. Multi-Year Guarantee Annuities (MYGA)
  3. Fixed Indexed Annuities (FIA)
  4. Market Value Adjustments (MVA)
  5. Two-tiered Annuities
  6. Guarantees/Benefits/Riders on Non-Variable based Annuity Contracts

- **Payout Annuities**
  1. Single Premium Immediate Annuities (SPIA)
  2. Deferred Income Annuities (DIA)
  3. Term Certain Payout Annuities
  4. Pension Risk Transfer Annuities (PRT)
  5. Structured Settlement Contracts (SSC)
  6. Longevity Reinsurance

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities and RILAs)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.F.of VM-22.

B. Effective Date & Transition

**Effective Date**

These requirements apply for valuation dates on or after January 1, 2024.

Commented [CD109]: Rigidly renumbering the sections. [10]
Commented [CD111]: Rigidly swapping the order. [18]
Commented [CD107]: The need to be revised to. [24]
Commented [CD123]: Grammar - delete the. [28]
Commented [CD125]: Would have space instead of add. [30]
Commented [CD127]: Delete the “&” and add “Annuities”. [31]
Commented [CD129]: Would this be “Non-Variable”? [32]
Commented [CD130]: Would this be “Annuities”? [33]
Commented [CD131]: for consistency make plural. [34]
Commented [CD132]: Words to address. [35]
Commented [CD133]: We suggest moving or deleting. [36]
Commented [CD134]: Would this belong in Scope? [40]
Commented [CD135]: Self-referencing “VM-22”. [38]
Commented [CD136]: Would this be an edit? [39]
Commented [CD137]: This should be edited. [41]
Commented [CD139]: Scan, suggest numbering. [42]
Commented [CD140]: Would this be an edit? [43]
Commented [X141]: We still have a question about. [44]
Transition

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the first three years following the effective date of VM-22 PBR. If a company during the three-year transition period elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.

Commented [X142]: Need to clarify what is meant by “VM-22 PBR Requirements”. Add specific section references, or update proposal to have the PBR and non-PBR sections of this VM-22 draft in different chapters. After having reviewed, we think it would be much more clear to reconsider the use of “VM-23” for the PBR requirements to avoid ambiguity around scope/exclusions. The non-PBR sections also just don’t seem to fit in this draft, and there is now ambiguity around whether other parts of VM-22 apply to them (scope, effective date, principles, etc.).

Commented [X143]: To be more clear, recommend adding “transition period” to “the three years”.

Commented [VM22144R143]: Edits to address this comment will be reflected in next exposure.

Commented [X145]: The effect of choosing to apply VM-22 PBR to a block of business on a prospective basis starting at least three years after the effective date of VM-22 PBR. If a company during the three-year transition period elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.

Commented [VM22146R145]: Discussed with Subgroup and decided to keep the VM-22 language silent on this issue, similar to VM-20, leaving it to be determined on a case-by-case basis for each state.

Commented [CD147]: Discussed with Subgroup and decided to not have early adoption before the start of the three year transition period.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve (SR) minus any applicable PIMR for those contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

D. The SR for a future valuation without the approval of the domiciliary commissioner.

Guidance Note: Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves, SRs, per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined The Additional Standard Projection Amount

D. The Stochastic Reserve

The stochastic reserve is determined by applying one of the two standard projection methods defined in Section 6. The same method must be used for all contracts within a group of contracts that are aggregated together to determine the reserve. The company shall elect which method they will use to determine the additional standard projection amount. The company may not change that election that are aggregated together to determine the reserve.

The stochastic reserve amount for any group of contracts shall be determined as CTE70 of the stochastic reserve (following the requirements of Section 4) plus the additional standard projection amount (following the requirements of Section 6) plus the SR for those contracts satisfying the Deterministic Certification Option, per the requirements in Section 3.E.

D. The SR

1. The SR shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.G herein.

2. The stochastic reserve amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve DR following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts within each Reserving Category as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles, SR. However, groups of contracts within different Reserving Categories may

Commented [X149]: Reinstall and modify later as needed- SPA being developed in separate workflow.
Commented [VM22150R149]: To address SPA later in the VM-22 development process.
Commented [X151]: One of the most confused parts of the draft was referring to a DR as the SR for certain contracts. Need to handle and refer to separately.
Commented [VM22152R151]: Edits to address this comment will be reflected in next exposure.

Commented [X153]: Guidance is needed on how a pre-reinsurance reserve is to be determined.

Commented [X154]: Reinstall and modify later as needed - SPA being developed in separate workflow.
Commented [VM22155R154]: Edits to address this comment will be reflected in next exposure.

Commented [CD156]: Should this be Section 3.G?
Commented [VM22157R156]: Edits to address this comment will be reflected in next exposure.

Commented [X158]: Recommend replacing “the scenario reserve” with “the deterministic reserve”. Note that we also disagree with calling the deterministic reserve a stochastic reserve (later in draft), which adds a good deal of confusion.
not be aggregated together in determining the SR. For the purposes of VM-22, Reserving Categories are classified as the following:

a. The “Payout Annuity Reserving Category” includes the following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits provided by variable annuities:
   i. Immediate annuity contracts;
   ii. Deferred income annuity contracts;
   iii. Structured settlements in payout or deferred status;
   iv. Fixed income payment streams resulting from the exercise of settlement options or annuitizations of host contracts issued;
   v. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest);
   vi. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts, once the contract funds are exhausted;
   vii. Certificates, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders fixed income payment streams upon their retirement; and
   viii. Pension Risk Transfer Annuities; and
   ix. Longevity Reinsurance.

b. The “Accumulation Reserving Category” are all annuities within scope of VM-22 under Section II of the NAIC Valuation Manual that are not in the “Payout Reserving Category”.

Using prudent actuarial judgement, consider the following elements when aggregating groups of contracts: whether groups of contracts are part of the same portfolio (or different portfolios that interact), same integrated risk management system, administered/managed together

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

5d. To the extent that these limits on the aggregation results in more than one model segment, the stochastic reserve SR shall equal the sum of the stochastic reserve SR amounts.

Commented [VM22159]: Include in deferred annuities with depleted fund value in payout reserving category or accumulation reserving category?

Commented [X160]: The term “Deterministic Certification Option” may be confusing, as there is no “deterministic” reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the phrasing to “with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E.”
E. Exclusion Test

1. To the extent that certain groups of contracts pass one of the definitional stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for immediate annuities specified in Section 13.

a. For dividend-paying contracts, a dividend liability shall be established following requirements in VM-A and VM-C, as described above, for the base contract.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018; AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on/after 2018; Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contracts may not group together contract types with significantly different risk profiles when performing the exclusion tests should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserve in Section D above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements using the method outlined in Section 4.2.3, with the exception of contract following Section 3.E which are to be calculated on a surrender basis.

G. Prudent Estimate Assumptions

1. With respect to the Stochastic Reserve SR in Section 3.D.C the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements in Section 12 of Model #820 and must periodicat least every 3 years review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary Company shall set a new, adequate, anticipated experience assumption for the factor.

3. To determine the prudent estimate assumptions, the stochastic reserve SR shall also follow the requirements in Sections 4 and general assumptions including Section 9 for asset assumptions, Section 10 for contract policy holder behavior assumptions, and Section 11 for mortality assumptions, and Section 12 for general guidance and expense assumptions.
H. Approximations, Simplifications, and Modeling Efficiency Techniques

A company may use simplifications, approximations, and modeling efficiency techniques to calculate the SR and/or the additional standard projection amount required by this section if the company can demonstrate that the use of such techniques does not understate the reserve by a material amount, and the expected value of the reserve calculated using simplifications, approximations, and modeling efficiency techniques is not less than the expected value of the reserve calculated that does not use them.

Guidance Note:

Examples of modeling efficiency techniques include, but are not limited to:

1. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters.
2. Generating a smaller liability or asset model to represent the full seriatim model using grouping compression techniques or other similar simplifications.

There are multiple ways of providing the demonstration required by Section 3.H. The complexity of the demonstration depends upon the simplifications, approximations or modeling efficiency techniques used. Examples include, but are not limited to:

1. Rounding at a transactional level in a direction that is clearly and consistently conservative or is clearly and consistently unbiased with an obviously immaterial impact on the result (e.g., rounding to the nearest dollar) would satisfy 3.H without needing a demonstration. However, rounding to too few significant digits relative to the quantity being rounded, even in an unbiased way, may be material and in that event, the company may need to provide a demonstration that the rounding would not produce a material understatement of the reserve.

2. A brute force demonstration involves calculating the minimum reserve both with and without the simplification, approximation or modeling efficiency technique, and making a direct comparison between the resulting reserve. Regardless of the specific simplification, approximation or modeling efficiency technique used, brute force demonstrations always satisfy the requirements of Section 3.H.

3. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters and providing a detailed demonstration of why it did not understate the reserve by a material amount and the expected value of the reserve would not be less than the expected value of the reserve that would otherwise be calculated. This demonstration may be a theoretical, statistical or mathematical argument establishing, to the satisfaction of the insurance commissioner, general bounds on the potential deviation in the reserve estimate rather than a brute force demonstration.

4. Justify the use of randomly sampling withdrawal ages for each contract instead of following the exact prescribed WDCM method by demonstrating that the random sampling method is materially equivalent to the exact prescribed approach, and the simplification does not materially reduce the Additional Standard Projection Amount and the final reported reserve. In particular, the company should demonstrate that the statistical variability of the results based on the random sampling approach is immaterial by testing different random sets, e.g., if randomly selecting a withdrawal age for each contract, the probability distribution of the withdrawal age should be stable and not vary.
Commented [X198]: Specific example should be tailored based on the SPA developed.

Commented [X199]: Added consistent with VM-21 Section 3.4, which was added to the 2022 VM.

Commented [VM2200R199]: Edits to address this comment will be reflected in next exposure.
Section 4: Determination of Stochastic Reserve SR

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Section 4.4 and 9. The company shall project cash flows including the following:

a. Revenue (gross premiums received by the company including gross premiums received from the policyholder) contract holder (including any due premiums as of the projected start date).

Guidance Note: If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset.

b. Other revenues, including contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).

c. All material benefits projected to be paid to contract policyholders—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.

Guidance Note: Amounts charged to account values on general account business are not revenue. Examples include rider charges and expense charges.

ad. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.1.

be. Insurance company expenses (including overhead and investment maintenance expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses) other acquisition expenses, associated with business in force as of the valuation date.

cf. Net cash flows associated with any reinsurance.

dg. Cash flows from hedging instruments as described in Section 4.4.4.
2. **Grouping of Index Crediting Strategies**

Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

3. **Model Cells**

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.
4. Modeling of Hedges

a. For a company that does not have a future hedging program tied directly to supporting the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

   a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

   b) No hedge positions— in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program tied directly to supporting the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

   a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders; contract holders.

   b) Existing hedging instruments that are currently held by the company for this purpose—offsetting the indexed credits— in support of the contracts falling under the scope of these requirements shall be included in the starting assets. Existing hedging instruments that are currently held by the company not for any other purpose—offsetting the indexed credits— should be modeled consistently with the requirements of Section 4.A.4.a.ii.

   c) An Index Credit Hedge Margin for these hedge instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible

Commented [X223]: Given that Section 9 covers hedging, we would suggest considering moving parts of Section 4.A.4 to that section.

Commented [X226]: VM-22 took out the CDHS requirement and replaced it with "future hedging program". Future hedging should not materially reduce reserves or TAR if it is not well documented. The hedging DG is currently working on this for VM-20/VM-21. We will work with VM-22 subgroup to edit VM-22 accordingly.

Commented [X227]: Suggest rewording "Future hedging program" to "hedging program with future transactions" to avoid ambiguity.

Commented [CD228]: The word "future" to describe the "hedging program" here is confusing. What about current hedging programs with expected future hedge purchases? Why not just say "hedging program"? Also, I wanted to note that removing the concept of CDHS creates inconsistency with both VM-20 and VM-21. Why not retain it?

Commented [CD229]: same comment as above, about the word "future" being confusing.

Commented [X230]: same comment as above.

Commented [VM22231R230]: This comment will be reflected in next exposure.

Commented [X232]: "Any other purpose" in the last sentence seems overly broad and should be narrowed.

Commented [CD230]: This comment will be reflected in next exposure.

Commented [X234]: Specify for this purpose as "not offsetting the indexed credits" and "for any other purposes" as "not for offsetting the indexed credits".

Commented [CD231]: This comment will be reflected in next exposure.

Commented [VM22235R234]: This comment will be reflected in next exposure.

Commented [VM22236R236]: Subgroup agreed to revisit this discussion after field testing.

Commented [CD238]: Elaborate verbiage by saying "hedging instruments" or "derivative instruments".

Commented [CD239]: This comment will be reflected in next exposure.
company experience and be no less than \([X\%]\) multiplicatively of the interest credited. In the absence of sufficient and credible company experience, a margin of \([Y\%]\) shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than \([Y\%]\). It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve \(SR\).

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future. Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine the stochastic reserve \(SR\) as the weighted average of two CTE values; first, a CTE70 ("best efforts") representing the company’s projection of all of the hedged cash flows, including future hedge purchases, and a second CTE70 ("adjusted") which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i., if the company has an indexed hedge program, the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.1.c, in both the "best efforts" run and the "adjusted" run.

d) The use of products not falling under the scope of PIR Section 1 through 13 requirements (e.g., variable annuities) [and, e.g., equity-indexed annuities] as a hedge shall not be recognized in the determination of accumulated deficiencies.

Guidance Note: Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other

Commented [X240]: It is not clear how the stress testing can be used to support the index credit hedge margin. It is a test of the modeled strategy not actual performance and does not reflect any model error. We suggest that both back testing and stress testing be required and elaborated further:

- Clearly specify method and metrics used for the back testing with focus on all available recent relevant history, not limited to 12 months.
- Recommend defined stress periods for stress testing, e.g., 2008 financial crisis, 2020 COVID impaired market conditions.

Commented [X241R240]: We will repeat the comment from our first letter: "Regarding hedge breakage expense assumptions, are both sources of error reflected here - error in the hedging itself, and error in the ability to accurately model it? Should we be separately considering the two limitations to make sure they are both clear: 1) the real-world hedging error and 2) the modeling error in reflecting the future hedging? Current error factor discussions seem muddled?"

Commented [X242]: Again, need to coordinate with Hedging DG.

Commented [X243]: Margins are discussed in a different section, so recommend deleting.

Commented [X244]: Edits were made to provide context and clarification for the requirements.

Commented [VM22245R244]: Edits to address this comment will be reflected in next exposure.

Commented [X246]: Edits to address this comment will be reflected in next exposure.

Commented [VM22247R246]: Edits to address this comment will be reflected in next exposure.

Commented [CD248]: It might be helpful to keep the parenthetical statement with "variable annuities" as the example.

Commented [VM22249R248]: Edits to address this comment will be reflected in next exposure.
fixed income assets supporting the contracts, and a margin is reflected rather than modeling using a CTE/70 adjusted run with no future hedge purchases. If a company has a more comprehensive hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or economic hedging), an appropriate and documented bifurcation method should be used in the application of sections 4.A.4.b.i and 4.A.4.b.ii above for the hedge modeling and justification. Such bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

Guidance Note: The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.

5. Revenue Sharing

If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each of the requirements set forth in VM-21 Sections 4.A.5.a through 4.A.5.5 are met.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods. Obligations remain at the end of the projection periods. Company can choose to run a shorter projection period but not shorter than 20 years and include the present value of the terminal benefits and expenses in the accumulated deficiency calculation.

7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. For a given scenario, the scenario reserve shall be determined using one of two methods described below:

   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defasement of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period.

Guidance Note: The greatest present value of accumulated deficiencies can be negative.
The scenario reserve for any given scenario shall not be less than the cash surrender value
with market value adjustment in aggregate on the valuation date for the group of contracts
modeled in the projection.

2. Discount Rates

In determining the scenario reserve, unless using the direct iteration method pursuant to
Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on
additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

a. The additional invested asset portfolio for a scenario is a portfolio of general
account assets as of the valuation date, outside of the starting asset portfolio, that
is required in that projection scenario so that the projection would not have a
positive accumulated deficiency at the end of any projection year. This portfolio
may include only (i) General Account assets available to the company on the
valuation date that do not constitute part of the starting asset portfolio; and (ii) cash
assets.

Guidance Note:

Additional invested assets should be selected in a manner such that if the starting asset portfolio were
revised to include the additional invested assets, the projection would not be expected to experience any
positive accumulated deficiencies at the end of any projection year.

It is assumed that the accumulated deficiencies for this scenario projection are known.

b. To determine the NAER on additional invested assets for a given scenario:

   i. Project the additional invested asset portfolio as of the valuation date to
the end of the projection period,

      a) Investing any cash in the portfolio and reinvesting all investment
proceeds using the company’s investment policy.

      b) Excluding any liability cash flows.

      c) Incorporating the appropriate returns, defaults and investment
expenses for the given scenario.

   ii. If the value of the projected additional invested asset portfolio does not
equal or exceed the accumulated deficiencies at the end of each projection
year for the scenario, increase the size of the initial additional invested
asset portfolio as of the valuation date, and repeat the preceding step.

   iii. Determine a vector of annual earned rates that replicates the growth in the
additional invested asset portfolio from the valuation date to the end of the

Commented [X260]: For products that do not have a cash surrender value, it is recommended that VM-22 use a
"working reserve" concept, similar to VM-21 Section 3.6
requirement. Otherwise, there will be an issue aggregating
those with and without CSV.

Commented [X261]: For products with market value
adjustment, needs to be floored at cash surrender value
with MVA.

Commented [X262]: We believe that assets held in the
separate account with performance not impacting
policyholder benefits should be modeled consistent with
how the business is managed.
projection period for the scenario. This vector will be the NAER for the given scenario.

iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.c, as a safe harbor.

Guidance Note: There are multiple ways to select the additional invested asset portfolio at the valuation date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

Treasury Department interest rate curves, as well as investment return paths for index funds, equities, and fixed income assets shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.

D. Projection of Assets

1. Starting Asset Amount
   a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:
      i. Any hedge instruments held in support of the contracts being valued; and
      ii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i).
   b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described

Commented [X263]: The wording “unreasonably high” is not clear or appropriate. Recommend this requirement be revised as part of a holistic fix to address extreme outliers in NAER both on the low and high side to handle anomalies for all of VM-20, VM-21, and VM-22. Some upper/lower cutoffs could be used that depend on scenario returns.

Commented [CD264]: “unreasonably high” is not well defined. Also, do we need to consider guardrails in the case of “unreasonably high” positive NAERs, not just negative NAERs?
above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets

For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

**Guidance Note:** Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets

a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:

i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;

ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the modeled company investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results...
in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the modeled aggregate reserve shall be the higher of that produced by the modeled company investment strategy and any non-prescribed asset spreads shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained by substituting fixed income reinvestment assets and have the same weighted average life (WAL) as the reinvestment assets in the modeled company investment strategy and are all public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 40% PBR credit rating 3 (Aa2/AA)

iii. 40% PBR credit rating 6 (A2/A)

iv. 40% PBR credit rating 9 (Baa/BBB)

c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism.

Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.ii and Section 4.D.4.a.iv, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.

Guidance Note: This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:

1850 M Street NW Suite 300 Washington, DC 20036 Telephone 202 223 8196 Facsimile 202 872 1948 www.actuary.org

© 2022 National Association of Insurance Commissioners 26
i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F as noted in 4.a.ii above.

b. Cash flows from account-index funds and general account equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.II.

E. Projection of Annuity Benefits

1. Assumed Annuitation Purchase Rates

a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such purchase rates shall reflect the payout rate specified in the contract.

b. For purposes of projecting future elective annuitization benefits (including annuitizations stemming from the election of a GMIB) and withdrawal amounts from GMWBs, the projected annuitization purchase rates shall be determined...
assessing that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuitzation Options
   a. For contracts projected to elect future annuitization options (including annuitizations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections may shall assume the contract will stay in force, the projected periodic payments are paid, and the associated maintenance expenses are incurred.

F. Frequency of Projection and Time Horizon
   1. Use of an annual cash-flow frequency (“timestep”) is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

   Care must be taken in simulating fee income and expenses when using an annual time step. For example, recognizing fee income at the end of each period after market movements, but prior to persistency decrements, would normally be an inappropriate assumption. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

   Guidance Note: As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs

When determining a stochastic reserve SR, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve. Additional standard projection amount the SR, DR, and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both the pre-reinsurance ceded and a post-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

Reflection of Reinsurance Cash Flows in the DR or SR

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve SR and DR shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

i. In this section, reinsurance includes retrocession, and assuming company includes retrocessionaire.

ii. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

iii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iv. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the stochastic reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the aggregate reserve by the absolute value of such reductions in surplus.
b. In order to determine the stochastic reserve $SR$ and $DR$, on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve $SR$ and $DR$ shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard cointertainment treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection based on using starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable method.

Guidance Note: For standard pro rata insurance treaties (do not include experience refunds), where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld cointertainment; modified cointertainment; cointertainment with a trust. To the extent these assets would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, modeling would partially default to the approach discussed for a standard cointertainment treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, Principle-Based Reserves for Life Products under the NAIC Valuation Manual, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsured policies belong and reflect the terms of the reinsurance agreement.

d. The company shall assume that the counterparties to a reinsurance agreement are knowledgeable about the contingencies involved in the agreement and likely to exercise the terms of the agreement to their respective advantage, taking into account the context of the agreement in the entire economic relationship between the parties. In setting assumptions for the NGE in reinsurance cash flows, the company shall include, but not be limited to, the following:

i. The usual and customary practices associated with such agreements.
ii. Past practices by the parties concerning the changing of terms, in an economic environment similar to that projected.
iii. Any limits placed upon either party’s ability to exercise contractual options in the reinsurance agreement.
iv. The ability of the direct-writing company to modify the terms of its policies in response to changes in reinsurance terms.
v. Actions that might be taken by a party if the counterparty is in financial difficulty.

3. Reserve Determined Upon Passing the Exclusion Test
If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance-ceded and post-reinsurance-ceded reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance-ceded reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance-ceded reserves might not, or vice versa.

4. Additional Standard Projection Amount

Where reinsurance is ceded, the additional standard projection amount shall be calculated as described in Section 6 to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties. The additional standard projection amount shall also be calculated pre-reinsurance ceded using the methods described in Section 6 but ignoring the effects of the reinsurance ceded.

Commented [VM22323R322]: Edits to address this comment will be reflected in next exposure
Commented [X322]: Both referring to reinsurance ceded should be clarified
Commented [VM22325R324]: Edits to address this comment will be reflected in next exposure
Commented [X324]: Ceded
Commented [VM22327R326]: Edits to address this comment will be reflected in next exposure
Commented [X326]: Ceded
Commented [VM22329R328]: Edits to address this comment will be reflected in next exposure
Commented [X328]: Opposite could also be true
Commented [VM22331R330]: Edits to address this comment will be reflected in next exposure
Commented [X330]: The current VM-21 language here does not work for VM-22 without needing to know the specific assumptions, etc., for the SPA
Commented [VM22331R332]: Edits to address this comment will be reflected in next exposure
Section 6: Standard Projection Amount To Be Determined

Commented [VM22332]: NY Comment Letter: Current CARVM standards should be a minimum floor for VM-22 policies, and only the stochastic reserve should permit grouping whereas the minimum floor should be seriatim.

Commented [X333]: SPA Section placement here still makes sense, but SPA under development.

Commented [VM2234R333]: Edit to update the title of this section will be reflected in next exposure.

Commented [VM22335]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.

Commented [X336]: SPA Section placement here still makes sense, but SPA under development.

Commented [VM22337]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.

Commented [NJ338]: Once this is written, the language from 4.A.1.a for longevity reinsurance could be added here as well, i.e. the standard projection would use net premiums based on the k factor approach, using the standard projection prescribed assumptions. Floor on std projection is at the contract level.
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation if the stochastic exclusion test (SET) is satisfied for each group of contracts. The company has the option to calculate or not calculate the SET.

   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then for each group of contracts that passes the SET, the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups of contracts. If the reserve methodology described in Section 4 is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.

   c. A company may not exclude a group of contracts from the stochastic reserve requirements if there are one or more future hedging programs supporting the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9.A.1.

   d. A company may elect to automatically exclude one or more groups of policies from the stochastic reserve calculation without passing the stochastic exclusion test (SET) if all of the following are met for all contracts in the group or groups:

      i. All of the contracts are either:
         - Single Premium Immediate Annuities,
         - Term Certain Payout Annuities, or
         - Structured Settlement Contracts;

      ii. None of the contracts are pension risk transfer annuities (PRT) or are covered under a longevity reinsurance agreement;

      iii. Future payout benefits are either level or stay within 5% of the initial payout benefit amount over time;

      iv. There is either no or an immaterial level of policyholder options permitted within the contracts; and

      v. The average [Macauley duration] of the liabilities of the contracts as measured from the issue date (or premium determination date) is less than [X].

B. Requirement to Pass the Type of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

Commented [X339]: need to modify exclusion testing section to reflect SPA.

Commented [NU340]: Longevity reinsurance likely to be scoped out of the stochastic reserve unless the stochastic reserve includes consideration of stochastic mortality. If it stays as stochastic interest only, then it probably does make sense that it would meet the exclusion testing. For exclusion testing, the k factor approach should continue to apply, and it should not be combined with other blocks of business.

Commented [X341]: Inconsistent groups vs. group references.

Commented [VM22342R341]: Edits to address this comment will be reflected in next exposure.

Commented [CD343]: Should this be "stochastic reserve" since Section 4 is about determining the stochastic reserve.

Commented [VM22344R343]: Follow Section 4 method of stochastic reserve for Section 3 aggregate reserve if not using the SET.

Commented [X345]: Decision is independent for each group the SET is performed on.

Commented [VM22346R345]: Edits to address this comment will be reflected in next exposure.

Commented [CD347]: Suggest deleting this highlighted part of the wording.

Commented [VM22348R347]: Edits to address this comment will be reflected in next exposure.

Commented [CD349]: See earlier comment about the phrase "future hedge program" being confusing.

Commented [X350]: Is "associated with the contracts" the same as the earlier use of "supporting the contracts"? Should the same wording be used here? If there is asset hedging for the assets supporting the contracts, it should be included. Need to define "solely supporting" index credits, and also have criteria on the effectiveness/error and documentation of any such hedging that is allowed for excluded business.

Commented [VM22351]: It is assumed that there is no asset hedging for the contracts. The Academy was voted to change this.

Commented [CD352]: Suggest renaming this section header/name to "Requirements to Pass the SET." There is only 1 SET, but 3 ways to pass it (SET, Demonstrated Certifications). The language gets confusing (here and elsewhere) when you start saying there are different "types" of SETs.
1. **Stochastic Exclusion Ratio Test (SERT)—**Annually within 12 months before the valuation date. Within 12 months before the valuation date, the company demonstrates that the groups of contracts pass the SERT defined in Section 7.C.

2. **Stochastic Exclusion Demonstration Test—**In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.

3. **SET Certification Method—**For groups of contracts that do not have guaranteed living benefits, future hedging programs, or pension risk transfer business, in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts does not have material aggregate risk levels across interest rate risk, mortality and/or longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

**Guidance Note:** The qualified actuary should develop documentation to support the actuarial certification that presents his or her analysis clearly and in detail sufficient for another actuary to understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not subject to material interest rate risk, mortality and/or longevity risk, or asset return volatility risk. Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:

a) A demonstration that, using requirements under VM-A and VM-C for the group of contracts, reserves calculated using requirements under VM-A and VM-C are at least as great as the assets required to support the group of contracts and certificates using the company’s cashflow testing model under each of the four (4) scenarios identified in this sub-section Section 7.C.1 or alternatively each of the New York seven scenarios economic scenarios, under each of the three mortality adjustment factors identified in Section 7.C.1.

b) A demonstration that the group of contracts passed the SERT within 36 months prior to the valuation date and the company has not had a material change in its interest rate risk, mortality and/or longevity risk, or asset return volatility risk.

c) A qualitative risk assessment of the group of contracts that concludes that the group of contracts does not have material interest rate risk, mortality and/or longevity risk, or asset return volatility risk. Such assessment would include an analysis of product guarantees, the company’s non-guaranteed elements (NGEs) policy, assets backing the group of contracts, the company’s longevity risk, and the company’s investment strategy.

---

C. **Stochastic Exclusion Ratio Test**

1. In order to exclude a group of contracts from the stochastic exclusion SR requirements under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of (b–a)/a is less than the greater of [x]% where x is the percentage change that would trigger the company’s materiality standard, where:

---

**Commented [CD354]:** Not sure why this part is deleted; suggest adding it back in.

**Commented [VM22355R354]:** Edits to address this comment will be reflected in next exposure.

**Commented [X356]:**

**Commented [VM22357R356]:** Subgroup voted in.

**Commented [VM22386R385]:**

**Commented [X387]:**

**Commented [VM22388R387]:**

**Commented [X389]:** The variability should be as...
Guidance Note: Note that the numerator should be the largest adjusted scenario reserve for any scenario other than the baseline economic scenario, minus the adjusted scenario reserve for the baseline economic scenario, and 100% as the adjustment factor for mortality. This is not necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100% as the adjustment factor for mortality, or the absolute value of the biggest difference from the adjusted scenario reserve for the baseline economic scenario excluding margins. Because mortality variability may differ by company, if the magnitude of the company’s margin for mortality exceeds 5%, then the company shall use the baseline mortality and the mortality augmented by plus and minus the company’s margin for this exercise.

2. In calculating the ratio in subsection 7.C.1 above:

   a. The company shall calculate an adjusted scenario reserve for the group of contracts for each of the 16 economic scenarios using the three levels of mortality adjustment factors that is equal to either (i) or (ii) below:

      i. The scenario reserve defined in Section 4, but with the following differences:

         a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph 7.C.1.b of this section.

         b) Using the interest rates and equity return assumptions specific to each scenario.

         c) Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.

         d) Shall reflect future mortality improvement in line with anticipated experience assumptions.

         e) Shall not reflect correlation between longevity and economic risks.

      ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:

         a) Using the interest rates and equity return assumptions specific to each scenario.

Commented [X390]: Correcting reference
Commented [VM22391R390]: Edits to address this comment will be reflected in next exposure
Commented [CD392]: Better to keep the reference to the full Section 7.C.1.4 above
Commented [VM22393R392]: Edits to address this comment will be reflected in next exposure
Commented [X394]: Correcting reference
Commented [VM22395R394]: Edits to address this comment will be reflected in next exposure
Commented [CD396]: Better to keep the reference to the full Section 7.C.1.4 above
Commented [VM22397R396]: Edits to address this comment will be reflected in next exposure
Commented [X398]: Need to modify in case largest result is just from the mortality stress on the same scenario
Commented [VM22399R398]: Edits to address this comment will be reflected in next exposure
Commented [X400]: Need to modify in case largest result is just from the economic stress on the same mortality level.
Commented [X401]: Need to ensure we have captured a prudent level of mortality variation for any given company in this test.
Commented [X402]: Updating to reflect mortality/economic scenario combinations.
Commented [X403]: For clarity
Commented [X404]: Be consistent with standard VM reference
Commented [VM22405R404]: Edits to address this comment will be reflected in next exposure
Commented [CD406]: Better to keep the reference to the full Section 7.C.1.4 above
Commented [VM22407R406]: Edits to address this comment will be reflected in next exposure
Commented [CD408]: Why delete this? Seems like it wouldn’t hurt to keep this language, for additional clarity
Commented [VM22409R408]: Edits to address this comment will be reflected in next exposure
Commented [X410]: Be consistent with standard VM reference
Commented [VM22411R410]: Edits to address this comment will be reflected in next exposure
Commented [CD412]: Better to reference the full Section 7.C.1.4 above
Commented [VM22413R412]: Edits to address this comment will be reflected in next exposure
b) Using the mortality scalars described in Paragraph Section 7.C.1.b of this section.

c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current available baseline economic scenario and the 15 other-economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.

e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the stochastic exclusion ratio test under on only a pre-reinsurance-ceded single basis upon determining the pre- or post-reinsurance reserved ceded aggregate reserve.

3. If the ratio calculated in this section is less than \([x]\)% pre-non-proportional reinsurance, but is greater than \([x]\)% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation • SERT = the ratio \((b-a)/a\) defined in Section 7.C.1 above

   a) The pre-non-proportional reinsurance results are “gross of non-proportional,” with a subscript “gn,” so denoted SERT\(_{gn}\)

   b) The post-non-proportional results are “net of non-proportional,” with subscript “nn,” so denoted SERT\(_{nn}\)

ii. If a block of business being tested is subject to one or more non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurance but ignoring the non-proportional contract(s), and “net of non-proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.
4. the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section and concluded that such certification could not legitimately be made.

b. Another more qualitative approach is to calculate the adjusted scenario reserves for the combined economic and mortality scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.

4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve requirements using the methodology in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

   a. The demonstration shall provide a reasonable assurance that if the stochastic reserve was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve requirements.

   b. If, as of the end of any calendar year, the company determines that the appropriate statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT SET for those contracts.

   c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an
E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve SR for a group of contracts using a single deterministic economic scenario, subject to the following conditions.

   a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies contracts and certificates. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recouping premium payments, and guaranteed living benefits.

   b. The company certifies that the group of policies contracts and certificates is not supported by a reinvestment strategy that contains future hedge purchases.

   c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing the scenario reserve volatility across various contracts. Company must pass the SERT when considering only the 16 economic scenarios paired with the 100% mortality scenario.
d. The company must disclose a description of contracts and associated features in the certification.

Drafting Note: Consider revisiting Paragraph E.1.e to possibly either require i) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario; or ii) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve $SR$ for the group of contracts under the Deterministic Certification Option is determined as follows:

a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).

b. The stochastic reserve $SR$ equals the scenario reserve following the requirements for Section 4.

Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.

Commented [X456]:

Commented [VM22457R456]: Subgroup agrees with including the 100% mortality scenario.

Commented [X458]: It may not be appropriate to use scenario 12 to calculate the scenario reserve for SPIA. See this article https://www.soa.org/sections/financial-reporting/financial-reporting-newsletter/2021/july/fr-2021-07-su/

“in an increasing interest rate environment for business where policyholder behavior is sensitive to prevailing interest rates, life insurers may face an increase in disintermediation risk (e.g., the risk of having to sell assets, potentially at a loss, to fund policyholder surrender benefits). For example, rising interest rates, particularly sudden jumps (e.g., New York 7 pop-up scenario with an immediate interest rate increase of 3 percent), may lead to higher actual and projected policyholder surrenders as policyholders seek out higher yielding investment opportunities. These increasing cash demands may require fixed income assets to be sold at depressed prices, and resultant projected losses (or lower gains) may result in reserve insufficiencies, necessitating the need for AAT reserves.”

Commented [X459]: Recommend deleting guidance note, as it doesn’t provide full or clear scope of what may be excluded, so could be misread to either guarantee option for certain products or exclude the option for other products.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Non-Index Credit Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company only hedges index credits. If the company only hedges index credit hedging from other hedging then only the section only pertains to the other hedging if the index hedging follows. In those situations, the modeling of hedging instruments can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.A.b.i.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the calculation of the stochastic reserve, determined in accordance with Section 3.D and Section 4.D.

3. The company shall take into account the costs and benefits of hedging positions expected to be held by the company in the future along each scenario. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than 6 months. Including the hedging strategy, used to implement the investment policy.

4. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. This also is referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which also is referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

5. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve, otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the \( \text{stochastic reserve}^\text{SR} \) otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the \( \text{stochastic reserve}^\text{SR} \) needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the \( \text{stochastic reserve}^\text{SR} \) attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock-tested.

Guidance Note: No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

C. Calculation of \( \text{Stochastic Reserve}^\text{SR} \) (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no future hedging purchases except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.i.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the \( \text{stochastic reserve}^\text{SR} \) is given by:

\[
\text{Stochastic reserve}^\text{SR} = \text{CTE70 (best efforts)} + E \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}]
\]
4. The company shall specify a value for $E$ (the "error factor") in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of $E$. The value of $E$ may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, $E$ must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recent available relevant period of data (but no less than 12 months), to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for $E$.

6. Such a back-test shall involve one of the following analyses:

a. For companies that model hedge cash flows directly ("explicit method"), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses—both realized and unrealized—observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g., reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

   To support the choice of a low value of $E$, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of $E$ by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an "implicit method" or "cost of reinsurance method"), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

   i. Determine the hedge asset gains and losses—both realized and unrealized—incur over the month attributable to equity, interest rate, and implied volatility movements.

   ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportions of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).
iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.

iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with less than 6 months of history, E should be at least 1.05. However, E may be lower than 1.05 if at least 6 months of reliable experience is available and/or if the change in strategy is a minor refinement rather than a material change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).
Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., > 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

8. The company shall set the value of E reflecting the extent to which the future hedging program is clearly defined. To support a value of E below 1.0, there should be very robust documentation outlining the future hedging program. To the extent that documentation outlining the future hedging program is incomplete, the value of E shall be increased. Any increases required to the value of E to reflect that documentation is not available to support that the future hedging program is clearly defined shall be in addition to increases to the value of E to reflect a lack of historical experience or to reflect the back-testing results.

E. Additional Considerations for CTE70 (best efforts)

If the company is following a CDHS, the fair value of the portfolio of contracts falling within the scope of these requirements shall be computed and compared to the CTE70 (best efforts) and CTE70 (adjusted). If the CTE70 (best efforts) is below both the fair value and CTE70 (adjusted), the company should be prepared to explain why this result is reasonable.

For the purposes of this analysis, the SR and fair value calculations shall be done without requiring the scenario reserve for any given scenario to be equal to or in excess of the cash surrender value in aggregate for the group of contracts modeled in the projection.

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for purposes of reducing the stochastic reserve (SR), the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions

Commented [X486]: Work is being done by the hedging DG. This is a placeholder. Need to reflect how clearly defined and well documented the hedge program is, to be able to rely on the backtesting provided. To the extent that hedge programs are not clearly defined, E should be increased to reflect that the backtesting cannot be relied on as an indicator of future effectiveness.

Commented [X487]:

Commented [VM22488R487]: Subgroup voted in favor of retaining the fair value disclosure wording here, which is only subject to non-index credit hedges at this point

Commented [CD489]:

Commented [VM22490R489]: Subgroup voted in favor of retaining the fair value disclosure wording here, which is only subject to non-index credit hedges at this point
on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or adverse estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited to, a hedging strategy where material hedging assets will be obtained when the fixed indexed annuity and other in-scope products account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets. There may be scenarios that are particularly costly to discontinuous hedging strategies, especially where those result in large discontinuous changes in sensitivities (Greeks) associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve SR, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve SR otherwise calculated.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the reserves level. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B and Section 12.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may or may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more material behavior assumptions, if relevant to the risks in the product, and thus the approach will not underestimate the reserve.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the company shall perform sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Account transfers.
- Future deposits.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently (but no less than every 3 years) when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
   b. Surrenders.
   c. Partial withdrawals (systematic and elective).
   d. Account transfers (switching/exchanges).
   e. Resets/ratchets of the guaranteed amounts (automatic and elective).
   f. Future deposits.
   g. Income start date for the benefit utilization.
   h. Commutation of benefit (from periodic payment to lump sum) or vice versa.

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions. For example:
   a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing, ) or if the contract provisions incentivize the contract holders to transfer between accounts.
   b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).
   c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

Guidance Note: For some non-elective benefits (nursing home benefits for example), unless relevant company experience exists to the contrary, the use of incidence rates greater than zero after the surrender charge has ended, or the cash value was depleted might be inappropriate may not be prudent since it would reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.
4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):
   a. Gender.
   b. Attained age.
   c. Issue age.
   d. Contract duration.
   e. Time to maturity.
   f. Tax status.
   g. Account value.
   h. Interest credited (current and guaranteed).
   i. Available indices.
   j. Guaranteed benefit amounts.
   k. Surrender charges, transaction fees or other contract charges.
   l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100% 
   
Commented [X526]: This also applies to VM-21, as there are fixed accounts. Is there any reason not to be consistent?
Commented [VM2527R526]: Only to focus on VM-22 for now
Commented [X528]: This is not a synonym (perhaps transaction fees is a subset of transaction fees) - why would transaction fees apply for VM-21, but only transfer fees for VM-22?
Commented [VM2529R528]: Edits to address this comment will be reflected in next exposure

Commented [X530]: This section states that “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally.” This text seems to directly contradict Section II. Reserve Requirements 6.H.2 which states: “When advantageous, policyholders will commence living benefit payouts if not started yet.” We suggest revising 6.H.2 to align with the text of 10.D.8.
efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holder stochastically modeled.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable appropriate to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practical allowance for appropriate simplifications, approximations and modeling efficiency techniques, the use of dynamic models is encouraged, but not mandatory. Static assumptions Risk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers), may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of behavior consistent with the economic scenarios and other variables in the model, including the non-scenario tested assumptions. The company shall test the sensitivity of results to understand the materiality of making alternate assumptions and follow the guidance discussed above on setting assumptions for sensitive behaviors.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution). To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the model) in order to determine exactly which scenario results are included in the CTE measure. Rather, in light of the products being valued, the company should be mindful of the general characteristics of those scenarios likely to represent the tail of the loss distribution and consequently use prudent estimate assumptions for behavior that are reasonable and appropriate in such scenarios. For non-variabilised annuities, these “valuation” scenarios would typically display one or more of the following attributes:
   a. Declining, increasing and/or volatile index values, where applicable.
   b. Price gaps and/or liquidity constraints.
   c. Rapidly changing Volatile interest rates or persistently low interest rates.
   d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions.
Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:
   a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.
   b. Complies with the contract holder behavior requirements stated in Section 10.A to Section 10.G above in this section.

2. If the company models policy loans explicitly, the company shall:
   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.
   b. Assign loan balances either to exactly match each policy’s contract’s utilization or to reflect average utilization over a model segment or sub-segments if the results are materially similar.
   c. Model policy loan interest in a manner consistent with policy contract provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
d. Model policy loan principal repayments, including those that occur automatically upon death or surrender. Include policy loan principal repayments as a positive policy loan cash flow, per Section 4.A.1.h.

e. Model additional policy loan principal. Include additional policy loan principal as a negative policy loan cash flow, per Section 4.A.1.h (but do not include interest added to the loan balance as a negative policy loan cash flow).

f. Model any investment expenses allocated to policy loans and include them either with negative policy loan cash flows or insurance expense cash flows.

I. Non-Guaranteed Elements

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy contract costs or values and are not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to non-variable annuities include but are not limited to the following: fixed credited rates on fixed accounts, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rolloup rates, rollover period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.I.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):

   a. The nature of contractual guarantees.

   b. The company’s past NGE practices and established NGE policies.

   c. The timing of any change in NGE relative to the date of recognition of a change in experience.

   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of NGE that:

   a. Is not based on some aspect of the policy’s or contract’s experience.

   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

However, if the board has guaranteed a portion of the NGE into the future, the former would seem more appropriate than the latter.
from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.

   a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve $SR$.

   b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve $SR$ should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the maximum reserve. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.)

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from similar industries or geographies that may be used to sub-divide inforce blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to...
B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2 for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

Guidance Note: Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.

4. Margin for Data Uncertainty

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) mortality (longevity) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a mortality (longevity) plus (minus) segment to a longevity (mortality) minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2 for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.
i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:

\[ q_x^{20XX+n} = q_x^{20XX}(1 - G_{2x})^n \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage (\( F_x \)) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual deferred annuities and deferred annuity contracts with guaranteed living benefits

\[ q_x^{2012+n} = q_x^{2012}(1 - G_{2x})^n + F_x \]

b. [1983 Table "a"] for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_x^{1994+n} = q_x^{1994}(1 - A_{x})^n \]

iii. For a business segment with non-U.S. insureds, when little or no experience or information is available on a business segment, an established industry or national mortality table and mortality improvement scale may be used, with approval from the domiciliary commissioner.

4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

a. Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

b. Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by

</tbody>
</table>
contract duration for an appropriate select period. As an alternative, if the company determines that mortality is affected by selection, the company could apply margins to the expected mortality in such a way that the actual mortality modeled does not depend on contract duration.

c. Modification and Relevance of Data

Even for a large company, the quantity of life exposures and deaths are such that a significant amount of smoothing may be required to determine expected mortality curves from mortality experience. Expected mortality curves, when applied to the recent historic exposures (e.g., three to seven years), should not result in an estimate of aggregate number of deaths less (greater) than the actual number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying data), older data may no longer be relevant. The “age” of the experience data used to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors that include, but are not limited to, trends in mortality experience, trends in exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative to mortality by amounts, changes in the mix of business and product features that could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves including margins for uncertainty with the mortality assumption assumptions described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

**Guidance Note:** For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the industry mortality assumption described in Section 11.B.3 used in the blending.

2. Adjustment of Statutory Valuation Industry Mortality for Improvement

For purposes of the adjustment for credibility, the industry mortality table for a plus segment may be and the industry mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective industry mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.
b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.

f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve SR. If such an adjustment would reduce the stochastic reserve SR, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Other Guidance and Requirements for Assumptions

A. Overview

This section provides guidance and requirements in general for setting prudent estimate assumptions when determining either the SR or DR. It also provides specific guidance and requirements for expense assumptions.

B. General Assumption Requirements

1. The company shall use prudent estimate assumptions for risk factors that are not stochastically modeled by applying margins to the anticipated experience assumptions if such risk factors have been categorized as material risks by following Section 1.B Principle 3 and requirements in Section 12.C.

2. The company shall establish the prudent estimate assumptions for risk factors in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

3. The company shall model the following risk factors stochastically unless the company elects the stochastic modeling exclusion defined in Section 7:
   a. Interest rate movements (i.e., Treasury interest rate curves).
   b. Equity performance (e.g., Standard & Poor’s 500 index [S&P 500] returns and returns of other equity investments).

4. If the company elects to stochastically model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.

Guidance Note: It is expected that companies will not stochastically model risk factors other than the economic scenarios, such as contract holder behavior or mortality, until VM-22 has more specific guidance and requirements available. Companies shall discuss with domiciliary regulators if they wish to stochastically model other risk factors.

5. The company shall use its own experience, if relevant and credible, to establish an anticipated experience assumption for any risk factor. To the extent that company experience is not available or credible, the company may use industry experience or other data to establish the anticipated experience assumption, making modifications as needed to reflect the circumstances of the company.
   a. For risk factors (such as mortality) to which statistical credibility theory may be appropriately applied, the company shall establish anticipated experience assumptions for the risk factor by combining relevant company experience with industry experience data, tables or other applicable data in a manner that is consistent with credibility theory and accepted actuarial practice.
b. For risk factors (such as utilization of guaranteed living benefits) that do not lend themselves to the use of statistical credibility theory, and for risk factors (such as some of the lapse assumptions) to which statistical credibility theory can be appropriately applied but cannot currently be applied due to lack of industry data, the company shall establish anticipated experience assumptions in a manner that is consistent with accepted actuarial practice and that reflects any available relevant company experience, any available relevant industry experience, or any other experience data that are available and relevant. Such techniques include:

i. Adopting standard assumptions published by professional, industry or regulatory organizations to the extent they reflect any available relevant company experience or reasonable expectations.

ii. Applying factors to relevant industry experience tables or other relevant data to reflect any available relevant company experience and differences in expected experience from that underlying the base tables or data due to differences between the risk characteristics of the company experience and the risk characteristics of the experience underlying the base tables or data.

iii. Blending any available relevant company experience with any available relevant industry experience and/or other applicable data using weightings established in a manner that is consistent with accepted actuarial practice and that reflects the risk characteristics of the underlying contracts and/or company practices.

c. For risk factors that have limited or no experience or other applicable data to draw upon, the assumptions shall be established using sound actuarial judgment and the most relevant data available, if such data exists.

d. For any assumption that is set in accordance with the requirements of Section 12.B.5.c, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing and disclose the analysis performed to ensure that the assumption is set at the conservative end of the plausible range.

e. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

6. The company shall sensitivity test risk factors that are not stochastically modeled and examine the impact on the stochastic reserve. The company shall update the sensitivity tests periodically as appropriate. The company may update the tests less frequently, but no less than every 3 years, when the tests show less sensitivity of the stochastic reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company
may perform sensitivity testing:

a. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.

b. Using data from prior periods.

**Guidance Note:** Sensitivity testing every risk factor on an annual basis is not required. For some risk factors, it may be reasonable, in lieu of sensitivity testing, to employ statistical measures for margins, such as adding one or more standard deviations to the anticipated experience assumption.

7. The company shall vary the prudent estimate assumptions from scenario to scenario within the stochastic reserve calculation in an appropriate manner to reflect the scenario-dependent risks.

C. Assumption Margins

The company shall include margins to provide for adverse deviations and estimation error in the prudent estimate assumption for each risk factor that is not stochastically modeled or prescribed, subject to the following:

1. The level of margin applied to the anticipated experience assumptions may be determined in aggregate or independently as discussed in Section 1.B Principle 3. It is not permissible to set a margin less toward the conservative end of the spectrum to recognize, in whole or in part, implicit or prescribed margins that are present, or are believed to be present, in other risk factors.

Risks that are stochastically modeled (e.g., interest rates, equity returns) or have prescribed margins or guardrails (e.g., assets, revenue sharing) shall be considered material risks. Other risks generally considered to be material include, but are not limited to, mortality, contract holder behavior, maintenance and overhead expenses, inflation and implied volatility. In some cases, the list of material risks may also include acquisition expenses, partial withdrawals, policy loans, annuitizations, account transfers and deposits, and/or option elections that contain an element of anti-selection.

2. The greater the uncertainty in the anticipated experience assumption, the larger the required margin, with the margin added or subtracted as needed to produce a larger Sr or DR than would otherwise result. For example, the company shall use a larger margin when:

   a. The experience data have less relevance or lower credibility.
   b. The experience data are of lower quality, such as incomplete, internally inconsistent or not current.
   c. There is doubt about the reliability of the anticipated experience assumption, such as, but not limited to, recent changes in circumstances or changes in company policies.
   d. There are constraints in the modeling that limit an effective reflection of the risk factor.
3. In complying with the sensitivity testing requirements in Section 12.6 above, greater analysis and more detailed justification are needed to determine the level of uncertainty when establishing margins for risk factors that produce greater sensitivity on the stochastic reserve.

4. A margin is permitted but not required for assumptions that do not represent material risks.

5. A margin should reflect the magnitude of fluctuations in historical experience of the company for the risk factor, as appropriate.

6. The company shall apply the method used to determine the margin consistently on each valuation date but is permitted to change the method from the prior year if the rationale for the change and the impact on the stochastic reserve is disclosed.

D. Expense Assumptions

1. General Prudent Estimate Expense Assumption Requirements

In determining prudent estimate expense assumptions, the company:

a. May spread certain information technology development costs and other capital expenditures over a reasonable number of years in accordance with accepted statutory accounting principles as defined in the Statements of Statutory Accounting Principles. 

Guidance Note: Care should be taken with regard to the potential interaction with the inflation assumption below.

b. Shall assume that the company is a going concern.

c. Shall choose an appropriate expense basis that properly aligns the actual expense to the assumption. If values are not significant, they may be aggregated into a different base assumption.

Guidance Note: For example, death benefit expenses should be modeled with an expense assumption that is per death incurred.

d. Shall reflect the impact of inflation.

e. Shall not assume future expense improvements.

f. Shall not include assumptions for federal income taxes (and expenses paid to provide fraternal benefits in lieu of federal income taxes) and foreign income taxes.

g. Shall use assumptions that are consistent with other related assumptions.

Guidance Note: Expense assumptions should reflect the direct costs associated with the block of contracts being modeled, as well as indirect costs and overhead costs that have been allocated to the modeled contracts.

h. Shall use fully allocated expenses.

i. Shall allocate expenses using an allocation method that is consistent across...
company lines of business. Such allocation must be determined in a manner that is within the range of actuarial practice and methodology and consistent with applicable ASOPs. Allocations may not be done for the purpose of decreasing the stochastic reserve.

i. Shall reflect expense efficiencies that are derived and realized from the combination of blocks of business due to a business acquisition or merger in the expense assumption only when any future costs associated with achieving the efficiencies are also recognized.

Guidance Note: For example, the combining of two similar blocks of business on the same administrative system may yield some expense savings on a per unit basis, but any future cost of the system conversion should also be considered in the final assumption. If all costs for the conversion are in the past, then there would be no future expenses to reflect in the valuation.

k. Shall reflect the direct costs associated with the contracts being modeled, as well as an appropriate portion of indirect costs and overhead (i.e., expense assumptions representing fully allocated expenses should be used), including expenses categorized in the annual statement as “taxes, licenses and fees” (Exhibit 3 of the annual statement) in the expense assumption.

l. Shall include acquisition expenses associated with business in force as of the valuation date and significant non-recurring expenses expected to be incurred after the valuation date in the expense assumption.

m. For contracts sold under a new policy form or due to entry into a new product line, the company shall use expense factors that are consistent with the expense factors used to determine anticipated experience assumptions for contracts from an existing block of mature contracts taking into account:

i. Any differences in the expected long-term expense levels between the block of new contacts and the block of mature contracts.

ii. That all expenses must be fully allocated as required under Section 12.D.1.h above.

2. Margins for Prudent Estimate Expense Assumptions

The company shall determine margins for expense assumptions following Section 12.C.
Section 13: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The allocation shall be made separately for DR and SR. The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

Table 12.1: Sample Allocation of Aggregate Reserve

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td></td>
<td>140</td>
</tr>
<tr>
<td>Allocation Basis for the excess of the Aggregate Reserve over the Cash Surrender Value ( A_i = \max( Ri - Ci, 0) )</td>
<td>10</td>
<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>

Commented [X627]: This method only makes sense if done separately for the DR and SR.
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

**Option 2: Actuarial Present Value Approach**

B. The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve \( SR \) defined in Section 3.D.

a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows, as well as any cash flows that are scenario dependent.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.

a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve \( SR \) defined in Section 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

<table>
<thead>
<tr>
<th>Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value</th>
<th>Li = (A1)/[Aggregate Reserve - 2C1]\</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.09</td>
<td>10.91</td>
</tr>
</tbody>
</table>

| Contract-level reserve Ci + Li | 37.09 | 50.91 | 52.00 | 140.00 |

Commented [X628]: This method depends on the NAER, so would not work for companies that use direct iteration.

Commented [X629]: This could give an unstable allocation if there is an even mix of products with different risk profiles, so that the tail is populated with some scenarios where Product A does poorly and some where Product B does poorly. The single scenario will only reflect the riskiness of one of the products.

Commented [X630]: Not just the NAER, but the cashflows are also scenario dependent.

Commented [VM22631R630]: Edits to address this comment will be reflected in next exposure.

Commented [CD632]: Section 3.D.

Commented [VM22633R632]: Edits to address this comment will be reflected in next exposure.

*Cash Surrender Value
**Guaranteed Lifetime Withdrawal Benefit

Guidance Note: The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 1314: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section and all contracts not passing the SET covered by Sections 1 through 13 of VM-22, are covered Section 14 of VM-22:
   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

   Guidance Note: For Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f and Section 1314.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:
   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f, Section 1314.A.2.g or Section 1314.A.2.h, the
4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 1314 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, *Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B)* (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in *Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C)* (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 1314.B.1.c above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   **Guidance Note:** If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.
3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.

4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her age last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 1314 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*
       *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.
   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

   | Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only

<table>
<thead>
<tr>
<th>Reference Period</th>
<th>Valuation Rate Bucket</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>6-10 years</td>
<td>C</td>
</tr>
<tr>
<td>11+ years</td>
<td>D</td>
</tr>
</tbody>
</table>

© 2022 National Association of Insurance Commissioners
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5 Years</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>90+</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>80–89</td>
<td>B</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>70–79</td>

</tr>
<tr>
<td>&lt; 70</td>
<td>D</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

2. Premium Determination Dates

a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d and A.2.e</td>
<td>Fixed payout annuities resulting from settlement options or annuitizations from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
<tr>
<td>A.2.g</td>
<td>Fixed income payment streams from CDAs, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
### Guidance Note

For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

<table>
<thead>
<tr>
<th>A.2.i</th>
<th>Group annuity and related certificates</th>
<th>Date consideration is determined and committed to by contract holder</th>
</tr>
</thead>
</table>

b. **Immaterial Change in Consideration**

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

### 3. Statutory Maximum Valuation Interest Rate

a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 1314.C.1) and its Premium Determination Date (Section 1314.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

d. **Quarterly Valuation Rate:**

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ I_q = R + S - D - E \]

Where:

a. \( R \) is the reference rate for that Valuation Rate Bucket (defined in Section 1314.C.4);

b. \( S \) is the spread rate for that Valuation Rate Bucket (defined in Section 1314.C.5);

c. \( D \) is the default cost rate for that Valuation Rate Bucket (defined in Section 1314.C.6);
and

d. E is the spread deduction defined as 0.25%.

e. Daily Valuation Rate:

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[ I_d = I_q + C_{d-1} - C_q \]

Where:

a. \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b. \( C_{d-1} \) is the daily corporate rate (defined in Section 1314.C.7) for the business day immediately preceding the premium determination date; and

c. \( C_q \) is the average daily corporate rate (defined in Section 1314.C.8) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate \( (I_d) \) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4. Reference Rate

Reference rates are updated quarterly as described below:

a. The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b. Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c. The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

5. Spread

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a. Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.1) effective for the calendar year in which the premium determination date falls.

6. Default costs for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on...
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAMLC1A0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAMLC2A0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAMLC3A0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAMLC4A0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAMLC7A0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAMLC8A0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 1314.C.7.a].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating Iq in Section 1314.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:

i. Bucket A:
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   b) Five-year certain only.

ii. Bucket B:
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   b) 10-year certain only.

iii. Bucket C:
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   c) 15-year certain only.

iv. Bucket D:
   a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
   b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for
individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

   a) Column 1 of Table 4 is identical to column 1 of Table 1.
   b) Column 2 of Table 4 is 50% of column 2 of Table 1.
   c) Column 3 of Table 4 is identical to column 2 of Table 4.
   d) Column 4 of Table 4 is 50% of column 3 of Table 1.
   e) Column 5 of Table 4 is identical to column 4 of Table 4.
   f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 3.1.4.1.2.i), the following apply:

a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

Guidance Note: Under some group annuity contracts, certificates may be purchased on different
b. In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

**Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.
Valuation Manual Section II| Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for non-variable annuity contracts issued prior to 1/1/2014 are those requirements as found in Sections 1 through 13 of VM-22.

D. Minimum reserve requirements for non-variable annuity contracts issued on or after Jan. 1, 2017, and on or before Dec. 31, 2017, are those requirements as found in Sections 1 through 12 of VM-22. The maximum valuation interest rate requirements for those contracts and fixed payout annuities are defined in Section 13 of VM-22, Statutory Maximum Valuation Interest Rates for Income Annuity Formulas.

E. Index or index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a subject for application of VM-22 requirements and are issued on 1/1/2024 and later are those requirements as found in Sections 1 through 13 of VM-22:

1. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.

2.b. Credits a rate of interest under the contract prior to the application of any market value adjustments that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

Guidance Note: Paragraph 2.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph 2.b prior to the application of any market value adjustments and Paragraph 2.a above, it may be appropriate to value such contracts under VM-22 requirements.

Minimum reserve requirements.
Index-linked or modified guaranteed annuity contracts or riders that do not satisfy either of the two conditions listed above criteria in Paragraph Section 2.E.1.i and Section 2.E.2 above and E.1.i may be a key consideration for application of VM-21 are issued on 1/1/2024 and later are those requirements as found in VM-21.

Commented [X652]: VM-21 specifically says “These requirements do not apply to contracts falling under the scope of VM-A-255: Modified Guaranteed Annuities; however, they do apply to contracts listed above that include one or more subaccounts containing features similar in nature to those contained in modified guaranteed annuities (MGAs) (e.g., market value adjustments).” Is this a contradiction?

Commented [X653]: Consistent with E above.

Commented [VM22654R653]: Edits to address this comment will be reflected in next exposure.
Subsection 6: Riders and Supplemental Benefits

Guidance Note: Designs of policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. Guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D.C. Any guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.

2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.

3. After issuance, the base policy or contract value or benefits are determined by referencing the base policy or contract features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

E. If a term life insurance rider on the named insured(s) on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is
separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.

**G.F.** For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

**H.G.** Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve (for VM-20 and VM-22) or TAR (for VM-21) if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves (for VM-20 and VM-22) or reserves and TAR (for VM-21) using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.

Commented [X661]: Simplifications are judged relative to reserves for VM-20/VM-21 and TAR for VM-22.

Commented [VM22662R661]: Edits to address this comment will be reflected in next exposure.

Commented [X663]: This section states that “When advantageous, policyholders will commence living benefit payouts if not started yet.” This text seems to directly contradict VM-22 Section 6.H.2 which states “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally”. We suggest revising 6.H.2 to align with the text of 10.D.8.
The format of this Definitions section is inconsistent with other parts of the VM. In VM-01 and VM-21, each defined term is numbered, and is defined in this format (for example):

1. The term "buffer annuity" is interchangeable with the term "registered index-linked annuity (RILA)", as defined in Section 1.D.?.

The term Buffer Annuity is not interchangeable to Registered Index-Linked Annuity (RILA) since Buffer Annuity is a subset of RILA. RILA can have different downside protections such as "Buffer" or "Floor". Recommend deleting Buffer Annuity or add descriptions for Buffer Annuity as a subtype in the RILA definition.

Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

The wording “after (or from)” the issue date used in the DIA and SPIA definitions is confusing. Recommend keeping it simple as “from” the issue date.

Is “typically” intended to be a requirement in the definition? That is, to qualify as FIA does there need to be guaranteed principle?

The definition of FIA describes the account value as typically with guaranteed principal. Since FIA always has the guaranteed principal, recommend deleting the wording “typically”.

Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

The wording “after (or from)” the issue date used in the DIA and SPIA definitions is confusing. Recommend keeping it simple as “from” the issue date.

Suggest striking sentence “Adverse mortality is typically expected for these contracts.” from definition. Additionally, it is possible that there may be non-substandard settlements.

The VM-22 Subgroup voted to adopted “Option 1” for Reserving Categories.
See Equitable comment letter: supports full aggregation, but if choosing between the two exposed options for two reserving categories, prefers option 2.

See NY comment letter: supports option 1, with additional category for “other” for any other contract with supporting assets such that there is greater reinvestment and longevity risks, than disintermediation risk and other risks associated with policyholder behavior as of the valuation date.

The reserving categories for VM-22 are not included in Scope. Recommend including the defined reserving categories in the section when outlining Scope.

We would support reworking this section to rely on principles, rather than definitions to determine what is in and out of scope. As product innovation continues, a simple list may not appropriately accommodate the applicability of this chapter. However, if such a list is included, then we believe it should align with the full list presented in Section 13.

ACLI will follow up with a proposed revision to the definitions and scope section

Edits to address this comment will be reflected in next exposure

suggest numbering the paragraphs within this section

Page 11: [18] Commented [CD111] CA DOI 12/30/2021 3:27:00 PM
suggest swapping the order of this section. That is, start with the "in scope" list, rather than the "out of scope" list.

Also, it seems like there should be specific mentions of GMDBs and GLBs, as there are in VM-21, since those guarantees can also be found on FIAs.

Edits to address this comment will be reflected in next exposure

Since buffer annuities are a subset of RILA, recommend deleting buffer annuities.

Edits to address this comment will be reflected in next exposure

Page 11: [22] Commented [CD115] CA DOI 12/30/2021 3:28:00 PM
this is not defined in the Definition section. should it be?
Edits to address this comment will be reflected in next exposure.

This needs to be revised to be in line with VM-21 Section 2.A. Consider removing "such as" list and adding a cross-reference to VM-21 Section 2.A.

Edits to address this comment will be reflected in next exposure.

should this be "non-variable annuities" since that is term used in Section 1.A?

Edits to address this comment will be reflected in next exposure.

Edits to address this comment will be reflected in next exposure.

Edits to address this comment will be reflected in next exposure.

should this be "Non-Variable Annuity"? Otherwise, should "Fixed Annuity" be defined in the Definitions section?

Edits to address this comment will be reflected in next exposure.

for consistency, make plural; i.e., change to "ies"

Edits to address this comment will be reflected in next exposure.
We suggest moving or deleting the sentence “The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.” from this section as it does not seem fitting here.
Page 15: [47] Commented [X163]  ACLI

Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest rates should be broader, if even necessary. Suggest editing as:

"these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A, and VM-C, and with the statutory maximum valuation rate for immediate annuities specified in Section 13."

Edits to address this comment will be reflected in next exposure

Page 15: [49] Commented [CD165]  CA DOI  12/30/2021 3:36:00 PM

Suggest rewording to just say "the stochastic exclusion test". There is only 1 SET, with 3 ways of passing it. Therefore, the current wording is confusion because it suggests that there are multiple SETs.

Edits to address this comment will be reflected in next exposure

Edits to address this comment will be reflected in next exposure

Page 15: [52] Commented [X169]  ACLI

We believe this guidance note is unnecessary as the intent of the section is clear, and the wording is possibly confusing.

Page 15: [53] Commented [X170]  TDI  11/9/2021 9:57:00 AM

The statement in this section is not acceptable as discussed in the previous TX comment letter. This will have the effect of potentially masking blocks that need PBR.

Subgroup agreed that wording for exclusion test aggregation should be consistent with VM-20. Edits to address this comment will be reflected in next exposure

Page 15: [55] Commented [X172]  ACLI

This section seems to indicate that the grouping of contracts in exclusion testing should be the same as the grouping of contracts for aggregation. This might cause fewer product types to be qualifying for exclusion if the test must be performed at a higher level of aggregation.

Subgroup voted to use wording consistent with VM-20, which prohibits aggregating contracts with significantly different risk profiles.

Page 15: [57] Commented [CD174]  CA DOI  12/30/2021 3:42:00 PM

for clarity, change this reference to "Section 3.D"

what is meant by "aggregate risk levels"? Aggregated across what? Need clarification on the intentions for adding this phrase, when it is not in VM-20. Otherwise, i would suggest deleting this.

Edits to address this comment will be reflected in next exposure

Page 35: [85] Commented [X366] TDI 11/18/2021 9:49:00 PM
This is not in VM-20 and would substantially change the exclusion. The intent is not to allow you to group a block that has material interest rate risk with a larger block that is insensitive to interest rate risks and thereby pass. If "aggregate" referred to potential compounding of interest rate, longevity, or asset risk then this could be redrafted to clearly call out a 4th category of risk due to a combination of the first three. However, I think this is already implicitly covered.

The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met June 14, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Mike Yanacheak (IA); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Mike Boerner and Yujie Huang (TX); and Craig Chupp (VA).

1. **Exposed the Longevity Reinsurance Proposal**

Ms. Eom shared the draft of the proposal for addressing longevity risk (Attachment Twenty-Two-A) in the proposed VM-22 framework as discussed during the Subgroup’s June 1 meeting. She proposed that longevity reinsurance be excluded from the payout annuity reserving category and be listed as a separate reserving category. She said the proposal recommends using net premiums instead of gross premiums for the calculation of longevity reinsurance accumulated deficiencies. The proposal recommends reducing the gross premiums by a k-factor to determine the net premium. She expressed openness to suggestions on how the k-factor is determined or alternative calculations that do not use a k-factor.

Mr. Carmello made a motion, seconded by Mr. Boerner, to expose the longevity reinsurance proposal for a 60-day public comment period ending Aug. 14. The motion passed unanimously.

2. **Discussed the Stochastic Exclusion Ratio Test**

Mr. Slutsker said that during the Subgroup’s June 1 meeting, the Academy agreed to review the proposal for using the VM-20, Requirements for Principle-Based Reserves for Life Products, approach for determining the numerator and denominator of the stochastic exclusion ratio test (SERT). Chris Conrad (American Academy of Actuaries—Academy) said the Academy has reviewed the proposal and agrees with the approach.

3. **Discussed Tier Two Comments on the Proposed VM-22 Framework**

Mr. Slutsker said the Texas Department of Insurance (TDI) proposes using the reinsurance language from VM-20 in Section 5 of the proposed VM-22 framework. Mr. Conrad said that while the Academy believes that the language is not necessary in a principle-based approach, it is comfortable with using the language in Section 5.

Mr. Slutsker said the TDI and the California Department of Insurance (DOI) proposes adding VM-21, Requirements for Principle-Based Reserves for Variable Annuities, language for fair value disclosures to the conditional tail expectations 70 (CTE-70) best efforts. Mr. Reedy said the language was added to be consistent with VM-21. Connie Tang (Prudential) said some clarifying notes may be needed because the methodology for some index credit products does not have “best efforts” versus “adjusted.” Al Zlogar (Academy) said that if the hedging program is only for index crediting, the proposed language is not needed. Mr. Slutsker said the language is in a section addressing non-indexed hedging strategies supporting guarantees. He said comments on whether it should be extended to all hedges can be submitted during the exposure period.

Mr. Slutsker said the proposed VM-22 framework lists the 1994 group annuity reserving table (1994 GAR) as the table a company should use if it has little pension risk transfer (PRT) mortality experience. He said the ACLI asked
if the mortality assumption can be based on third-party data rather than an industry table. He said the question is also pertinent to the credibility section of the proposal. Ms. Eom asked how state insurance regulators might get comfortable with the data from a third party. Mr. Bayerle said the ACLI will give that some thought. Mr. Carmello said the Subgroup should require a prescribed table. The Subgroup voted not to allow the use of third-party data.

Having no further business, the VM-22 (A) Subgroup adjourned.
RESERVING CATEGORY DEFINITIONS

The term “Payout Annuity Reserving Category” includes the following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits provided by variable annuities. For the purposes of the “Payout Annuity Reserving Category”, Longevity Reinsurance shall be excluded from the following categories of contracts, certificates and contract features:

1. Immediate annuity contracts;
2. Deferred income annuity contracts;
3. Structured settlements in payout or deferred status;
4. Fixed income payment streams resulting from the exercise of settlement options or annuitizations of host contracts issued;
5. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest);
6. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts, once the contract funds are exhausted;
7. Certificates, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders fixed income payment streams upon their retirement; and
8. Pension Risk Transfer Annuities; and

The term “Longevity Reinsurance Reserving Category” refers to Longevity Reinsurance under the definition provided in [VM-01 or VM-22 Section 1.d of the Valuation Manual].

The term “Accumulation Reserving Category” are all annuities within scope of VM-22 under Section II of the NAIC Valuation Manual that are not in the “Payout Reserving Category” or “Longevity Reinsurance Reserving Category”.

Drafting Note: Intent is to not permit aggregation between longevity reinsurance and other contracts for VM-22 PBR calculations.
**Section 4: Determination of SR**

A. **Projection of Accumulated Deficiencies**

1. **General Description of Projection**

   The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Sections 4 and 9. The company shall project cash flows including the following:

   a. **Gross premium** received by the company from the contract holder (including any due premiums as of the projected start date). **For purposes of Longevity Reinsurance, net premium shall be used in the projection and defined as the gross premium multiplied by a “K-factor,” where the K-factor is determined as:**

      i. The present value of the expected future benefits at contract inception using the prudent estimate assumptions determined at contract inception and an interest rate equal to the prescribed interest rate under VM-A and VM-C, divided by item ii immediately below.

      ii. The present value of the expected future gross premiums at contract inception using the prudent estimate assumptions determined at contract inception and an interest rate equal to the prescribed interest rate under VM-A and VM-C.

      iii. The resulting amount is capped at 1, in other words the application of the K-factor shall not result in the net premium exceeding the gross premium.

   **Guidance Note:** If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset.

   b. **Other revenues**, including contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses). **For purposes of Longevity Reinsurance, it is not expected that any such other revenues will apply. To the extent there are other revenues, they should be included with item ii under a immediately above so that the calculation of the K-factor includes all expected future revenues from the contract holder.**

   c. **All material benefits projected to be paid to contract holders**—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.
b. d. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.I.

c. e. Insurance company expenses (including overhead and maintenance expense),
commissions and other acquisition expenses associated with business in force as of
the valuation date.

d. f. Cash flows associated with any reinsurance.

e. g. Cash flows from hedging instruments as described in Section 4.A.4.

f. h. Cash receipts or disbursements associated with invested assets (other than policy
loans) as described in Section 4.D.4, including investment income, realized capital
gains and losses, principal repayments, asset default costs, investment expenses,
asset prepayments, and asset sales.

If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest
income, new loan payments and principal repayments.
The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met June 1, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Vincent Tsang (IL); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Mike Boerner and Yujie Huang (TX); Tomasz Serbinowski (UT); and Craig Chupp (VA).

1. **Discussed the VM-22 Draft Comment Tracker**

   Mr. Slutsker said a drafting discussion log (Attachment Twenty-Three-A) has been created to track Subgroup progress on comments received on the proposed VM-22 framework (Attachment Twenty-Three-B).

2. **Discussed Tier Two Comments on the Proposed VM-22 Framework**

   Mr. Slutsker reviewed the list of VM-22 framework discussion topics (Attachment Twenty-Three-C). He said the American Council of Life Insurers (ACLI) questioned whether single premium immediate annuities (SPIAs) should be allowed the option to use the Commissioners Annuity Reserve Valuation Method (CARVM) without having to pass an exclusion test to avoid having to do principle-based reserving (PBR). Brian Bayerle said that in general, SPIAs will pass the exclusion test and do not carry any significant risk not captured by CARVM. Ms. Eom agreed with allowing the option to automatically exclude SPIAs but suggested that the exclusion would only apply to vanilla SPIAs. Mr. Chupp asked if the rates currently in VM-22, Statutory Maximum Valuation Interest Rates for Income Annuities, would be applicable. Mr. Bayerle confirmed that would be the case. Mr. Tsang agreed with using the pre-PBR methodology but said the exclusion should only apply prospectively. Mr. Carmello said that once the company selects the option, it should not be able to reverse it. He said he would prefer that instead of providing an option, the Subgroup should decide whether to exempt SPIAs from PBR. Chris Conrad (American Academy of Actuaries—Academy) said the Academy believes that SPIAs should be subjected to exclusion testing. He said SPIAS with terms greater than 20 years would potentially fail the exclusion test because they have greater reinvestment risk. He said the Academy intends to include SPIA exclusion testing in the VM-22 field study to determine if 20 years is the right cutoff. Mr. Chupp recommended basing the eligibility for exclusion testing on an average duration threshold instead of the length of the term. Subgroup members voted unanimously to allow SPIAs to automatically pass the exclusion test. The Subgroup then unanimously voted to limit the automatic pass to SPIAs with liability durations less than a certain threshold to be determined by the Subgroup. Mr. Slutsker said he will work with Mr. Chupp, Ms. Eom, and Mr. Carmello to determine if additional criteria are needed. Mr. Conrad agreed that the Academy would work to determine the appropriate durations for the threshold, as well as analyze how the automatic pass might affect the deterministic reserve.

Mr. Bayerle said the ACLI supports using the certification method for pension risk transfer (PRT) business. Ms. Eom said she is considering proposing additional language to reflect the influence of mortality on PRT contracts. Mr. Conrad said the Academy excluded PRT business from the certification method due to the potentially long durations of PRT business. Subgroup members voted to retain the language that prohibits PRT business to use the certification method.

Mr. Slutsker said the Texas Department of Insurance (TDI) suggested that the product grouping for exclusion testing should be similar to the grouping for PBR modeling. He said that the aggregation of blocks of business with
significantly different risk profiles would not be allowed. He said the ACLI favors allowing products to be grouped in alignment with the payout and accumulation categories determined for non-variable annuities. Mr. Bayerle said that aggregating on a higher level will force more products into stochastic modeling. Subgroup members agreed with the approach suggested by the TDI.

Mr. Slutsker said the TDI recommended having products pass, not merely disclose, the 16 scenarios from the exclusion ratio test to be eligible for the deterministic reserve. The Subgroup voted, with Mr. Chupp abstaining, to require that products pass the 16 scenarios to be eligible for the deterministic reserve.

Having no further business, the VM-22 (A) Subgroup adjourned.

Subsection 6: Riders and Supplemental Benefits ........................................ 8329

Commented [X2]: Note that part of the 2022 VM updates was to replace all instances of "stochastic reserve" with "SR" other than the initial definition in VM-01.
Section 1: Background

A. Purpose

Sections 1 through 13 of these requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2024. Section 14 of these requirements establishes the maximum valuation rate for payout annuities for contracts issued on or after 1/1/2018. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts and certificates, the Commissioners Reserve Valuation Method (CRVM).

Guidance Note: CRVM requirements apply to some group pension contracts.

B. Principles

The projection methodology used to calculate the stochastic reserve SR is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves.

Guidance Note: The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

Principle 1: The objective of the approach used to determine the stochastic reserve SR is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

Principle 2: The calculation of the stochastic reserve SR is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cash-flow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve SR at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

Guidance Note: Examples where full aggregation between contracts may not be possible include experience rated group contracts and the operation of reinsurance treaties.

Principle 3: The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the...
company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the stochastic reserve $SR$ at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve $SR$, the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

**Guidance Note:** The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle. More guidance and requirements for setting assumptions in general are provided in Section 12.

**Principle 4:** While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve $SR$ is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

**Principle 5:** Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve $SR$. Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve $SR$ without also reducing risk on scenarios similar to those used in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

**C. Risks Reflected**

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and
   b. Capable of materially affecting the reserve.

**Commented [X11]:** We suggest deleting the sentence "Generally, assumptions are..." since it does not provide guidance. We also suggest tightening the remainder of the text for clarity.

**Commented [X12]:** Need general assumption guidance section

**Commented [X13]:** Principle 5 has the statement "nor a method based on factors calibrated to the results of a cash flow scenario model" which is intended for the Alternative Methodology in VM-21. The statement should be deleted from VM-22.

**Commented [X14]:** We recommend deleting the third sentence (starting with "Therefore, the use of assumptions...") because this lacks historical context and is covered by the final sentence.

**Commented [X15]:** Consistent with our comments on 1.B, we would support consistent application of risks reflected across all chapters, rather than embedding the language in each chapter. Were this to be retained in VM-22, we would suggest maintaining consistency with VM-23 to avoid any confusion.

**Commented [CD16]:** VM-21 has “… and Risks Not Reflected” in this section header, which should be retained here since the section on risks not reflected is still in here.
2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:

a. Asset risks
   i. Credit risks (e.g., default or rating downgrades).
   ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).
   iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).
   iv. Performance of equities, real estate, and Schedule BA assets.
   v. Call risk on callable assets.
   vi. Separate account fund performance.
   vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).
   viii. Currency risk.

b. Liability risks
   i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.
   ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.
   iii. Utilization risk associated with guaranteed living benefits.
   iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.
   v. Annuitization risks.
   vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).
   vii. Applicable expense risks, including fluctuation in maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks
   i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.
   ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).

Commented [CD17]: Can a non-variable annuity have a separate account fund? I am not aware of any such annuity. Furthermore, all references to separate accounts and fund performance were deleted from this draft. Thus, we should consider deleting this item from the list.

Commented [CD18]: Is there a distinction between “dump-ins” and “deposits”? Why are both words needed? Also, if it’s determined that both words are needed, should this same change be made in VM-21?

Commented [X19]: Recommend change to “fluctuation in” maintenance expenses for clarity.

Commented [CD20]: should this same change also be made to VM-21?

Commented [X21]: We recommend removing the bullet “Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above” as this is unclear and probably extraneous.
iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:
   a. Those not associated with the policies or contracts being valued, or their supporting assets.
   b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
      i. Liquidity risks associated with a sudden and significant levels of withdrawals and surrenders “run on the bank.”
   b. Liability risks
      i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.
      ii. Catastrophic events (e.g., epidemics or terrorist events).
      iii. Major breakthroughs in life extension technology that have not yet fundamentally altered recently observed mortality experience.
      iv. Significant future reserve increases as an unfavorable scenario is realized.
   c. General business risks
      i. Deterioration of reputation.
      ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.
      iii. Poor management performance.
      iv. The expense risks associated with fluctuating amounts of new business.
      v. Risks associated with future economic viability of the company.
      vi. Moral hazards.
      vii. Fraud and theft.
      viii. Operational.
      ix. Litigation.
D. Specific Definitions for VM-22

**Buffer Annuity**
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

- **Deferred Income Annuity (DIA)**
  An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin one year 13 months or later after (or from) the issue date if the contract holder survives to a predetermined future age.

- **Fixed Indexed Annuity (FIA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, subject to certain limits, typically with guaranteed principal.

- **Flexible Premium Deferred Annuity (FPDA)**
  An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

- **Funding Agreement**
  A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

- **Guaranteed Investment Contract (GIC)**
  Insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

- **Index Credit Hedge Margin**
  A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

- **Index Credit**
  Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to contractpolicy values that is linked to an index or indices. Amounts credited to the contractpolicy resulting from a floor on an index account are included.

Commented [X31]: It seems the definitions included in this section are largely only used for the purpose of establishing the Scope in Section 2. Since this is intended to be a principles-based methodology, recommend a strong definition of “Fixed Annuity” instead of specific product underneath this business. The first paragraph in A. Scope seems to provide this with specific references which are out of scope. If changing the scope section, we would suggest deleting the various product definitions if not used elsewhere; if these definitions are potentially applied beyond VM-22, we would suggest moving any necessary definitions to VM-01

Commented [CD32]: The format of this Definitions section is inconsistent with other parts of the VM. In VM-01 and VM-21, each defined term is numbered, and is defined in this format (for example): 1. The term “buffer annuity” is interchangeable with the term “registered index-linked annuity (RILA)”, as defined in Section 1.D.7.

Commented [X33]: The term Buffer Annuity is not interchangeable with Registered Index-Linked Annuity (RILA) since Buffer Annuity is a subset of RILA. RILA can have different downside protections such as “Buffer” or “Floor”; recommend deleting Buffer Annuity or add definitions for Buffer Annuity as a subtype in the RILA definition.

Commented [X34]: Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline #1, rather than the 1 year that currently is in the VM-22 draft.

Commented [X35]: The wording “after (or from)” the issue date used in the DIA and SPIA definitions is confusing; recommend keeping it simple as “from” the issue date.

Commented [X36]: Is “typically” intended to be a requirement in the definition? That is, to qualify as FIA does there need to be guaranteed principal?

Commented [CD37]: insert: “subject to certain limits,”

Commented [X38]: The definition of FIA describes the account value as typically with guaranteed principal. Since FIA always has the guaranteed principal, recommend deleting the wording “typically.”

Commented [CD39]: should be "contract"

Commented [CD40]: should be "contract"
• **Index Crediting Strategy**
The strategy defined in a contract to determine index credits for a contract. This refers for example, this may refer to underlying index, index parameters, date, timing, performance triggers, and other elements of the crediting method.

• **Index Parameter**
Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

• **Longevity Reinsurance**
An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

• Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

• Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

• **Market Value Adjustment (MVA) Annuity**
An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

• **Modified Guaranteed Annuity (MGA)**
A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values and death benefits that are based upon a market-value adjustment formula if held for shorter periods.

---

Commented [X41]: We would suggest adding performance trigger to the list, along with other potential crediting methods; alternatively, the definition could specify that the crediting methods listed are examples only.

Commented [X42]: The definition states that “Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition.” Why is this the case and does this imply that longevity swaps are not within the scope of VM-22? Recommend adding to the out of scope list in “2.A. Scope” if that is the case. Clarification would also be helpful on what guidance should be used for these agreements if out of scope for VM-22. Further, we would suggest removing “typically” from the definition.

Commented [VM2243R42]: Target resolving definition of longevity reinsurance prior to addressing NJ comment letter on using a potential net premium method.

Commented [VM2244]: New Jersey comment letter: due to future premiums, longevity reinsurance may generate negative reserves, which can be used to eliminate or reduce other immediate annuity reserves. Suggest using net premium methodology, solving for k-factor at issue to solve for PV(premiums) = PV(benefits).

Commented [VM2245R44]: Target resolving definition of longevity reinsurance prior to addressing NJ comment.
- **Multiple-Year Guaranteed Annuity (MYGA)**
  A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple-year guarantee period.

- **Pension Risk Transfer (PRT) Annuity**
  An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

- **Registered Index-Linked Annuity (RILA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

- **Single Premium Immediate Annuity (SPIA)**
  An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within 13 months from the issue date.

- **Single Premium Deferred Annuity (SPDA)**
  An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.

- **Stable Value Contract**
  A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

- **Structured Settlement Contract (SSC)**
  A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

- **Synthetic Guaranteed Investment Contract (Synthetic GIC)**

Commented [CD48]: should this be “Multi-Year” instead of “Multiple Year”? The former is the more commonly used term for MYGA

Commented [CD49]: "fixed annuity" is not defined. Is it better to change all instances of “fixed annuity” to “non-variable annuity” to be consistent with the terminology introduced in Section 1.A (and to be aligned with the actual VM-22 chapter name)? An alternative could be to add a definition for “fixed annuity”, with the definition of it being a “non-variable annuity”

Commented [CD50]: ok to keep this as “multiple year”

Commented [XS1]: Is “typically” intended to be a requirement in the definition? That is, to qualify as PRT must the insurance company have the asset risk? Consistent with the comment on Longevity Reinsurance, it would be helpful to clarify where a longevity swap contract falls within these definitions. Notably, index-based longevity swaps should be out of scope as they do not meet definition of “annuity contract” in SSAP 50. It should also be made explicit that PRT contracts can include lump sum benefits, death benefits and cash balance benefits as well.

Commented [XS2]: It is unclear to us why RILA is defined in VM-22 when it is being used to exclude the product from VM-22 requirements.

Commented [XS3]: Is it intended to address Buffer Annuity (not sure this is needed) can add here as a subset of RILA?

Commented [XS4]: Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline #K, rather than the 1 year that currently is in the VM-22 draft.

Commented [XS5]: The wording “after (or from)” the issue date used in the DIA and SPIA definitions is confusing. Recommend keeping it simple as “from” the issue date.

Commented [XS6]: Suggest striking sentence “Adverse mortality is typically expected for these contracts” from definition. Additionally, it is possible that there may be non-standard settlements.

Commented [CD57]: suggest spelling out GIC first, followed by the acronym
Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the contract policyholder or plan trust.

- **Term Certain Payout Annuity**
  A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

- **Two-Tiered Annuity**
  A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.

The term “cash surrender value” means, for the purposes of these requirements, the amount available to the contract holder upon surrender of the contract. Generally, it is equal to the account value less any applicable surrender charges, where the surrender charge reflects the availability of any free partial surrender options. However, for contracts where all or a portion of the amount available to the contract holder upon surrender is subject to a market value adjustment, the cash surrender value shall reflect the market value adjustment consistent with the required treatment of the underlying assets. That is, the cash surrender value shall reflect any market value adjustments where the underlying assets are reported at market value, but it shall not reflect any market value adjustments where the underlying assets are reported at book value.

The term “guaranteed minimum death benefit” (GMDB) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount; or (ii) exceeds the minimum amount and is:

- increased by an amount that may be either specified by or computed from other policy or contract values; and
- has the potential to produce a contractual total amount payable on such death that exceeds the account value; or
- in the case of an annuity providing income payments, guarantees payment upon such death of an amount payable on death in addition to the continuation of any guaranteed income payments.

E. **Materiality**

The company shall establish a standard containing the criteria for determining whether an assumption, risk factor, or other element of the principle-based valuation has a material impact on the size of the reserve. This standard shall be applied when identifying material risks.

Section 2: **Scope and Effective Date**

1850 M Street NW  Suite 300  Washington, DC 20036  Telephone 202 223 8196  Facsimile 202 872 1948  www.actuary.org

© 2022 National Association of Insurance Commissioners
A. Scope

Subject to the requirements of this Sections 1 to 13 of VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

Products in scope of VM-22 include non-variable annuities which consist of, but are not limited to, the following list:

- Account Value Based Annuities
  1. Deferred Annuities (SPDA & FPDA)
  2. Multi-Year Guarantee Annuities (MYGA)
  3. Fixed Indexed Annuities (FIA)
  4. Market Value Adjustments (MVA)
  5. Two-tiered Annuities
  6. Guarantees/Benefits/Riders on Non-Variable Annuity Contracts

- Payout Annuities
  1. Single Premium Immediate Annuities (SPIA)
  2. Deferred Income Annuities (DIA)
  3. Term Certain Payout Annuities
  4. Pension Risk Transfer Annuities (PRT)
  5. Structured Settlement Contracts (SSC)
  6. Longevity Reinsurance

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities and RILAs)
2. GICs
3. Synthetic GICs
4. Stable Value Contracts
5. Funding Agreements

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.F of VM-22.

B. Effective Date & Transition

Effective Date

These requirements apply for valuation dates on or after January 1, 2024.
Transition

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the first three years following the effective date of VM-22 PBR. If a company during the three-year transition period elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.

Commented [X84]: Need to clarify what is meant by “VM-22 PBR Requirements”. Add specific section references, or update proposal to have the PBR and non-PBR sections of this VM-22 draft in different chapters. After having reviewed, we think it would be much more clear to reconsider the use of “VM-23” for the PBR requirements to avoid ambiguity around scope/exclusions. The non-PBR sections also just don’t seem to fit in this draft, and there is now ambiguity around whether other parts of VM-22 apply to them (scope, effective date, principles, etc.).

Commented [X85]: To be more clear, recommend adding “transition period” to “the three years”.

Commented [X86]: Can a company wait until the end of the transition period to start PBR, but then apply PBR to the issues from during the transition period? This was unclear for VM-20, and still seems unclear here. Need to be explicit one way or the other.

Commented [CD87]: Will we (or should we) allow for any early adopters (like we did for VM-21)? It would seem reasonable to us to consider accommodating early adopters.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve, SR (following the requirements of Section 4) plus the additional standard projection amount (following the requirements of Section 6) plus the DR for those contracts satisfying the Deterministic Certification Option, less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

**Guidance Note:** Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves, SRs, per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined: The Additional Standard Projection Amount

D. The Stochastic Reserve

The stochastic reserve

The additional standard projection amount is determined by applying one of the two standard projection methods defined in Section 6. The same method must be used for all contracts within a group of contracts that are aggregated together to determine the reserve. The company shall elect which method they will use to determine the additional standard projection amount. The company may not change that election for a future valuation without the approval of the domiciliary commissioner.

E. The SR

1. The SR shall be determined on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.GE herein.

2. The stochastic reserve, SR, amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserves, DR following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles, SR

Commented [X88]: Reinstall and modify later as needed - SPA being developed in separate workflow.

Commented [X89]: One of the most confused parts of the draft was referring to a DR as the SR for certain contracts. Need to handle and refer to separately.

Commented [X90]: Guidance is needed on how a pre-reinsurance reserve is to be determined.

Commented [X91]: Reinstall and modify later as needed - SPA being developed in separate workflow.

Commented [CD92]: Should this be Section 3.G?

Commented [X93]: Recommend replacing “the scenario reserve” with “the deterministic reserve”. Note that we also disagree with calling the deterministic reserve a stochastic reserve (later in draft), which adds a good deal of confusion.
a. Aggregate in a manner that is consistent with the company’s risk management strategy and reflect the likelihood of any change in risk offsets that could arise from shifts between product types, and

b. Using prudent actuarial judgment, consider the following elements when aggregating groups of contracts: whether groups of contracts are part of the same portfolio (or different portfolio that interact), same integrated risk management system, administered managed together

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

4. To the extent that those limits on the aggregation result in more than one model segment, the stochastic reserve SR shall equal the sum of the stochastic reserve SR amounts computed for each model segment and scenario reserve DR amounts computed for each model segment for which the company elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test

1. To the extent that certain groups of contracts pass one of the defined stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology pursuant to applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for immediate annuities specified in Section 13.

   a. For dividend-paying contracts, a dividend liability shall be established upon following requirements in VM-A and VM-C, as described above, for the base contract.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018, AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on or after 2018, Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contract company may not group together contract types with significantly different risk profiles when performing the exclusion tests should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserves in Section D above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements using the method outlined in Section 4.2.3, with the exception of contract following Section 3.E which are to be calculated on a per-policy basis.

G. Prudent Estimate Assumptions:

1. With respect to the Stochastic Reserve SR in Section 3.DC, the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements

Commented [X94]: As we have seen with VM-20, these types of extremely fuzzy requirements lead to full aggregation. If full aggregation is the intent, just explicitly allow it. We do recommend granular disclosures of the aggregation benefit for FIAs w/o GLBs, FIAs w/o GLBs, PDA w/o GLBs, SPIAs, PRT, DIA, and SSL.

Commented [VM229R904]: In addition, consider full comment letter about longevity reinsurance, and how this fits into the above categories.

Commented [X96]: The term “Deterministic Certification Option” may be confusing, as there is no “deterministic” reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the phrasing to “with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E.”

Commented [X97]: Recommend replacing “the scenario reserve” with “the deterministic reserve”. Note that we also disagree with calling the deterministic reserve a stochastic reserve (later in draft), which adds a good deal of confusion.

Commented [CD98]: suggest expanding header to “Stochastic Exclusion Test”, for clarity

Commented [X90]: Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest rates should be broader, if even necessary. Suggest editing as:

   ‘these groups of contracts may be valued using the methodology and statutory maximum valuation rate’

Commented [CD100]: Suggest rewording to just say “the stochastic exclusion test”. There is only 1 fixed, with 3

Commented [X101]: Typo. Delete for clarity

Commented [X102]: We believe this guidance note is unnecessary as the intent of the section is clear, and

Commented [X103]: The statement in this section is not acceptable as discussed in the previous TX comment

Commented [X104]: This section seems to indicate that the grouping of contracts in exclusion testing should

Commented [CD105]: For clarity, change this reference to “Section 3.D”

Commented [CD106]: Again, suggest rewording this to just say “the stochastic exclusion test”

Commented [X107]: Based on VM-20 language.

Commented [X108]: Either in this item or in Section 12 allocation to contracts not covered by PBR method

Commented [X109]: This sub-section seems more appropriate in Section 4 (or pulled out completely)

Commented [CD110]: VM-21 Section 3.H on simplifications, approximations, and modeling efficiency

Commented [CD111]: should this be “Section 3.D”?
in Section 12 of Model #820 and must periodically at least every 3 years review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

3. To determine the prudent estimate assumptions, the stochastic reserve (SR) shall also follow the requirements in Sections 4 and general assumptions including Section 9 for asset assumptions, Section 10 for contract policy holder behavior assumptions, and Section 11 for mortality assumptions, and Section 12 for general guidance and expense assumptions.

H. A company may use simplifications, approximations, and modeling efficiency techniques to calculate the SR and/or the additional standard projection amount required by this section if the company can demonstrate that the use of such techniques does not understate the reserve by a material amount, and the expected value of the reserve calculated using simplifications, approximations, and modeling efficiency techniques is not less than the expected value of the reserve calculated that does not use them.

**Guidance Note:**

Examples of modeling efficiency techniques include, but are not limited to:

1. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters.
2. Generating a smaller liability or asset model to represent the full seriatim model using grouping compression techniques or other similar simplifications.

There are multiple ways of providing the demonstration required by Section 3.H. The complexity of the demonstration depends upon the simplifications, approximations or modeling efficiency techniques used. Examples include, but are not limited to:

1. Rounding at a transactional level in a direction that is clearly and consistently conservative or is clearly and consistently unbiased with an obviously immaterial impact on the result (e.g., rounding to the nearest dollar) would satisfy 3.H without needing a demonstration. However, rounding to too few significant digits relative to the quantity being rounded, even in an unbiased way, may be material and in that event, the company may need to provide a demonstration that the rounding would not produce a material understatement of the reserve.
2. A brute force demonstration involves calculating the minimum reserve both with and without the simplification, approximation or modeling efficiency technique, and making a direct comparison between the resulting reserve. Regardless of the specific simplification, approximation or modeling efficiency technique used, brute force demonstrations always satisfy the requirements of Section 3.H.

Commented [X112]: Recommend to periodically review at least every three years.

Commented [CD113]: Should this be “the company... shall”, rather than the “qualified actuary... shall”? Not sure why this particular task falls on the QA, when “the company” generally has responsibility for PBR and, in the subsection directly before this one, the company is assigned the task of establishing prudent estimate assumptions.

Commented [X114]: Suggest replacing “if the results of statistical testing or other testing” with “if the results of the review” to simplify language and avoid possible confusion.

Commented [X115]: Recommend replacing “the qualified actuary” with “the Company” consistent with general PBR requirements that the company set assumptions.

Commented [CD116]: should this be “the company”?

See prior comment.

Commented [CD117]: should this be “contract holder”?

Commented [X118]: Need a new section for the general assumptions, including specifics for the expense assumptions. APF currently exposed for VM-21. We should be consistent with any edits.
3. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters and providing a detailed demonstration of why it did not understate the reserve by a material amount and the expected value of the reserve would not be less than the expected value of the reserve that would otherwise be calculated. This demonstration may be a theoretical, statistical or mathematical argument establishing, to the satisfaction of the insurance commissioner, general bounds on the potential deviation in the reserve estimate rather than a brute force demonstration.

4. Justify the use of randomly sampling withdrawal ages for each contract instead of following the exact prescribed WDCM method by demonstrating that the random sampling method is materially equivalent to the exact prescribed approach, and the simplification does not materially reduce the Additional Standard Projection Amount and the final reported reserve. In particular, the company should demonstrate that the statistical variability of the results based on the random sampling approach is immaterial by testing different random sets, e.g., if randomly selecting a withdrawal age for each contract, the probability distribution of the withdrawal age should be stable and not vary significantly when using different random number sets.

Commented [X119]: Specific example should be tailored based on the SPA developed.

Commented [X120]: Added consistent with VM-21 Section 3.H, which was added to the 2022 VM.
Section 4: Determination of Stochastic Reserve (SR)

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Sections 4 and 9. The company shall project cash flows including the following:

- **A. Revenue:** Gross premium received by the company including gross premiums received from the policyholder (policyholder, contract holder) including any due premiums as of the projected start date.

  **Guidance Note:** If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset.

- **b. Other revenues:** including contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).

- **c. All material benefits:** projected to be paid to contract holders—reflecting the impact of all guarantees and adjusted to take into account amounts associated with business inforce as of the valuation date. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.

  **Guidance Note:** Amounts charged to account values on general account business are not revenues; examples include rider charges and expense charges.

- **d. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.**

- **e. Insurance company expenses (including overhead and investment maintenance expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses), other acquisition expenses, associated with business inforce as of the valuation date.**

- **f. Cash flows associated with any reinsurance.**

- **g. Cash flows from hedging instruments as described in Section 4.A.4.**

- **h. Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains, and other acquisition expenses.**

**Commented [CD121]:** Should this refer to Section 4 and Section 9?

**Commented [CD122]:** “contract holder”?

**Commented [X123]:** If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset. This needs to be clarified - see guidance note added below. Recommend specifying the revenue in this bullet to be gross premium since there are other revenue items that are discussed in other bullets.

**Commented [CD124]:** “contract holders”?

**Commented [X125]:** The purpose of this guidance note is not clear as these charges would be reflected in the cash flows.

**Commented [CD126]:** should this be Section 10.1?

**Commented [X127]:** Changed investment expense to be maintenance expense so that it does not repeat what is included in bullet h.

**Commented [X128]:** Added acquisition expenses.

**Commented [X129]:** Take out the revenues that covers the investment expenses and added a separate bullet under bullet “a” for other revenues.

**Commented [CD130]:** Both net and gross cash flows have to be considered, so I don’t agree with the addition of “Net” here.
gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.

**Guidance Note:** Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance).

**Guidance Note:** Section 4.A.1 requires market value adjustments (MVAs) on liability cash flows to be reflected because in a cash flow model, assets are assumed to be liquidated at market value to cover the cash outflow of the cash surrender; therefore, inclusion of the market value adjustment aligns the asset and liability cash flows. This may differ from the treatment of MVAs in the definition of cash surrender value (Section 1.D), which defines the statutory reserve floor for which the values must be aligned with the annual statement value of the assets.

2. **Grouping of Index Crediting Strategies**

Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

3. **Model Cells**

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.

4. **Modeling of Hedges**
a. For a company that does not have a future hedging program tied directly to supporting the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

b) No hedge positions, in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program tied directly to supporting the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders;

b) Existing hedging instruments that are currently held by the company for this purpose, offsetting the indexed credits, shall be included in the starting assets. Existing hedging instruments that are currently held by the company for any other purpose, offsetting the indexed credits, should be modeled consistently with the requirements of Section 4.4.4.a.ii.

c) An Index Credit Hedge Margin for these hedge instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible company experience and be no less than [X%] multiplicatively of
the interest credited. In the absence of sufficient and credible company experience, a margin of [Y%] shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than [Y%]. It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve SR.

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future. Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve SR as the weighted average of two CTE values: first, a CTE/70 (“best efforts”) representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE/70 (“adjusted”) which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i., if the company has an indexed credit hedging program, the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.i.c., in both the “best efforts” run and the “adjusted” run.

d) The use of products not falling under the scope of Section 1 through 13 requirements (e.g., variable annuities) as a hedge shall not be recognized in the determination of accumulated deficiencies.

[Guidance Note: Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other fixed income assets supporting the contracts, and a margin is reflected rather than modeling using]
a CTE70 adjusted run with no future hedge purchases. If a company has a more comprehensive
hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or
economic hedging), an appropriate and documented bifurcation method should be used in the
bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities
versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

Guidance Note: The requirements of Section 4.A.4 govern the determination of reserves for annuity
contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the
use of derivative instruments for hedging purposes and should not be used in determining whether a
company is permitted to use such instruments in any state or jurisdiction.

5. Revenue Sharing

If applicable, projections of accumulated deficiencies may include income from projected
future revenue sharing, net of applicable projected expenses (net revenue-sharing income)
if such only following the requirements set forth in VM-21 Section 4.A.5.a through
4.A.5.f. Commented [X150]: Unclear why Revenue Sharing is considered for non-variable products, can probably delete.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so
that no materially greater reserve value would result from longer projection periods.
Obligations remain at the end of the projection periods. Company can choose to run a
shorter projection period but not shorter than 20 years and include the present value of the
terminal benefits and expenses in the accumulated deficiency calculation.

7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow
testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. For a given scenario, the scenario reserve shall be determined using one of two methods
described below:

a) The starting asset amount plus the greatest present value, as of the projection start
date, of the projected accumulated deficiencies; or

b) The direct iteration method, where the scenario reserve is determined by solving
for the amount of starting assets which, when projected along with all contract cash
flows, result in the deformance of all projected future benefits and expenses at the
end of the projection horizon with no positive accumulated deficiencies at the end
of any projection year during the projection period.

Guidance Note: The greatest present value of accumulated deficiencies can be negative.

Commented [X151]: Clarify that for revenue sharing, the entire subsection of VM-21 Section 4.A.5 applies.

Commented [CD152]: The "requirements are met" list is only in Section 4.A.5.a. Was the intent also to define the
amount of net revenue-sharing income allowed in the projections? If so, will need to add verbiage to reference

Commented [X153]: We recommend that the projection period requirement be in line with that of VM-20. Instead
of meeting the immateriality requirement, calculate the present value of the terminal benefits and expenses and
include it in the accumulated deficiency calculation.

Commented [VM22154]: See Bill Wilton’s comment letter, expressing opposition to inclusion of pre-tax IMR.

Commented [CD155]: should we consider these changes to VM-21 as well, for consistency?

Commented [X156]: Section does not specify what the reserve floor shall be (if any) for contracts without cash
surrender value.
The scenario reserve for any given scenario shall not be less than the cash surrender value with market value adjustment in aggregate on the valuation date for the group of contracts modeled in the projection.

2. Discount Rates

In determining the scenario reserve, unless using the direct iteration method pursuant to Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

a. The additional invested asset portfolio for a scenario is a portfolio of general account assets as of the valuation date, outside of the starting asset portfolio, that is required in that projection scenario so that the projection would not have a positive accumulated deficiency at the end of any projection year. This portfolio may include only (i) General Account assets available to the company on the valuation date that do not constitute part of the starting asset portfolio; and (ii) cash assets.

Guidance Note:

Additional invested assets should be selected in a manner such that if the starting asset portfolio were revised to include the additional invested assets, the projection would not be expected to experience any positive accumulated deficiencies at the end of any projection year.

It is assumed that the accumulated deficiencies for this scenario projection are known.

b. To determine the NAER on additional invested assets for a given scenario:

i. Project the additional invested asset portfolio as of the valuation date to the end of the projection period,

   a) Investing any cash in the portfolio and reinvesting all investment proceeds using the company’s investment policy.

   b) Excluding any liability cash flows.

   c) Incorporating the appropriate returns, defaults and investment expenses for the given scenario.

ii. If the value of the projected additional invested asset portfolio does not equal or exceed the accumulated deficiencies at the end of each projection year for the scenario, increase the size of the initial additional invested asset portfolio as of the valuation date, and repeat the preceding step.

iii. Determine a vector of annual earned rates that replicates the growth in the additional invested asset portfolio from the valuation date to the end of the projection period.
projection period for the scenario. This vector will be the NAER for the given scenario.

iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.c, as a safe harbor.

Guidance Note: There are multiple ways to select the additional invested asset portfolio at the valuation date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

Treasury Department interest rate curves, as well as investment return paths for index funds, equities, and fixed income assets shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.

D. Projection of Assets

1. Starting Asset Amount

a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:

i. Any hedge instruments held in support of the contracts being valued; and

ii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i).

b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described

Commented [X160]: The wording “unreasonably high” is not clear or appropriate. Recommend this requirement be revised as part of a holistic fix to address extreme outliers in NAER both on the low and high side to handle anomalies for all of VM-20, VM-21, and VM-22. Some upper/lower cutoffs could be used that depend on scenario returns.

Commented [CD161]: “unreasonably high” is not well defined. Also, do we need to consider guardrails in the case of “unreasonably high” positive NAERs, not just negative NAERs?
above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets

For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

Guidance Note: Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets

a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:

i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;

ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the modeled company investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results

Commented [X162]: This change was adopted for VM-20 and VM-21 for the 2022 VM.
in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the modeled aggregate reserve shall be the higher of that produced by the modeled company investment strategy and any non-prescribed asset spreads, shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained by substituting an alternative investment strategy in which all fixed income reinvestment assets have the same weighted average life (WAL) as the reinvestment assets in the modeled company investment strategy and are all public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 70% PBR credit rating 3 (Aa2/AA)

iii. 45% PBR credit rating 6 (A2/A)

iv. 40% PBR credit rating 9 (Baa/BBB)

c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.iii and Section 4.D.4.a.iv, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.

**Guidance Note:** This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:

---

Commented [CD161]: should this be “stochastic reserve”, since this is within Section 4: Determination of Stochastic Reserve

Commented [X164]: This change was adopted for VM-20 and VM-22 for the 2022 VM.

Commented [CD165]: Suggest making this plural (“Treasures”) to be consistent with Section 13.B.9

Commented [X166]: The proposed reinvestment mix comes from a different assumption context in current VM 22, i.e., it is designed to calculate the maximum allowed valuation interest rates, while the reinvestment mix for VM 22 PBR draft is to put a guardrail around the fixed income reinvestment assets. A guardrail is not intended to identify outliers and should not be tied to an average. The biggest concern is with the higher allocation percentage in BBB assets. The valuation manual should build an appropriate level of conservatism in the valuation standards instead of reflecting industry trends. By moving from VM-20 and VM-21 required mix of 50%/50% AAA/A to the proposed mix, the gross spreads increased by 20-30 bps for almost all VM. We do not object to using a lower credit quality guardrail to get rid of any excessive conservatism. We recommend considering and comparing with other alternative allocations, something between the current and the proposed, e.g., 20% AA and 80% A. This will help regulators make informed decisions. In any case, we should be consistent with VM-20 and VM-21. If a change is made, it needs to be for all three.

Commented [CD167]: These references should be Section 4.D.3.a.iii and 4.D.3.a.iv

---

1850 M Street NW Suite 300 Washington, DC 20036 Telephone 202 223 8196 Facsimile 202 872 1948 www.actuary.org

© 2022 National Association of Insurance Commissioners
i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F, as noted in 4.a.ii above.

b. Cash flows from general account-index funds and general account equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.H.

E. Projection of Annuitization Benefits

1. Assumed Annuitization Purchase Rates

a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such purchase annuity rates shall reflect the payout rate specified in the contract.

b. For purposes of projecting future elective annuitization benefits (including annuitizations stemming from the election of a GMIB) and withdrawal amounts from GMWBs, the projected annuitization purchase rates shall be determined...
assuming that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuitization Options
   a. For contracts projected to elect future annuitization options (including annuitizations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections may assume the contract will stay in force, the projected periodic payments are paid, and the associated maintenance expenses are incurred.

F. Frequency of Projection and Time Horizon
   1. Use of an annual cash-flow frequency ("timestep") is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

Care must be taken in simulating fee income and expenses when using an annual time step. For example, recognizing fee income at the end of each period after market movements, but prior to persistency decrements, would normally be an inappropriate assumption. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

Guidance Note: As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs

When determining a stochastic reserve, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve, additional standard projection amount—the SR, DR, and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both a post-reinsurance ceded and a pre-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

Reflection of Reinsurance Cash Flows in the DR or SR

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve SR and DR shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

i. In this section, reinsurance includes retrocession, and assuming company includes retrocessionaire.

ii. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

iii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iv. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the stochastic aggregate reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum aggregate reserve by the absolute value of such reductions in surplus.
b. In order to determine the stochastic reserve SR and DR on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserves SR and DR shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard coinsurance treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection based on using starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable method.

Guidance Note: For standard pro-rata insurance treaties (does not include experience refunds), where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld coinsurance; modified coinsurance; coinsurance with a trust. To the extent these assets would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard coinsurance treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, Principle-Based Reserves for Life Products under the NAIC Valuation Manual, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsured policies belong and reflect the terms of the reinsurance agreement.

d. The company shall assume that the counterparties to a reinsurance agreement are knowledgeable about the contingencies involved in the agreement and likely to exercise the terms of the agreement to their respective advantage, taking into account the context of the agreement in the entire economic relationship between the parties. In setting assumptions for the NGE in reinsurance cash flows, the company shall include, but not be limited to, the following:

i. The usual and customary practices associated with such agreements,

ii. Past practices by the parties concerning the changing of terms, in an economic environment similar to that projected,

iii. Any limits placed upon either party’s ability to exercise contractual options in the reinsurance agreement,

iv. The ability of the direct-writing company to modify the terms of its policies in response to changes in reinsurance terms,

v. Actions that might be taken by a party if the counterparty is in financial difficulty.

3. Reserve Determined Upon Passing the Exclusion Test
If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance-ceded and post-reinsurance-ceded reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance-ceded reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance-ceded reserves might not, or vice versa.

4. Additional Standard Projection Amount

Where reinsurance is ceded, the additional standard projection amount shall be calculated as described in Section 6 to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties. The additional standard projection amount shall also be calculated pre-reinsurance ceded using the methods described in Section 6 but ignoring the effects of the reinsurance ceded.

---

Commented [X191]: Both referring to reinsurance ceded. Should be clarified.

Commented [X192]: ceded

Commented [X193]: ceded

Commented [X194]: Opposite could also be true.

Commented [X195]: The current VM-21 language here looks to work for VM-22 without needing to know the specific assumptions, etc., for the SPA.
Section 6: To Be Determined

Commented [VM22196]: NY Comment Letter: Current CARVM standards should be a minimum floor for VM-22 policies, and only the stochastic reserve should permit grouping whereas the minimum floor should be seriatim.

Commented [X197]: SPA Section placement here still makes sense, but SPA under development.

Commented [VM22198]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve SR calculation if the stochastic exclusion test (SET) is satisfied for each of the group of contracts. The company has the option to calculate or not calculate the SET.

   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then for each group of contracts that passes the SET, the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups.

   c. A company may not exclude a group of contracts from the stochastic reserve SR requirements if there are one or more future hedging programs associated with supporting the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9.A.1.

B. Requirement to Pass the Types of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

1. Stochastic Exclusion Ratio Test (SERT)—Annually within 12 months before the valuation date, the company demonstrates that you have met the criteria described in Section 4 for those groups.

2. Stochastic Exclusion Demonstration Test—In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.

3. SET Certification Method—For groups of contracts that do not have guaranteed living benefits, future hedging programs, or pension risk transfer business, in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts is not subject to material interest rate risk, mortality and/or longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

Guidance Note: The qualified actuary should develop documentation to support the actuarial methodology that presents his or her analysis clearly and in detail sufficient for another actuary to understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not subject to material interest rate risk, mortality and/or longevity risk, or asset return volatility risk.
Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:

a) A demonstration that, using requirements under VM-A and VM-C for the group of contracts, reserves calculated using requirements under VM-A and VM-C are at least as great as the assets required to support the group of contracts and certificates using the company’s cash-flow testing model under each of the 4416 economic scenarios identified in this section, Section 7.C.1 or alternatively each of the New York seven economic scenarios, under each of the three mortality adjustment factors identified in Section 7.C.1.

b) A demonstration that the group of contracts passed the SERT within 36 months prior to the valuation date and the company has not had a material change in its interest rate risk, mortality and/or longevity risk, or asset return volatility risk.

c) A qualitative risk assessment of the group of contracts that concludes that the group of contracts does not have material interest rate risk, mortality and/or longevity risk, or asset return volatility. Such assessment would include an analysis of product guarantees, the company’s non-guaranteed elements (NGEs) policy, assets backing the group of contracts, the company’s longevity risk, and the company’s investment strategy.

C. Stochastic Exclusion Ratio Test

1. In order to exclude a group of contracts from the stochastic reserve SR requirements under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of (b–a)/a is less than the greater of [x]% and the percentage change that would trigger the company’s materiality standard, where:

   a. \( a \) = the adjusted scenario reserve described in Paragraph 7.C.2.a below using economic scenario \( k \) and 100% as the adjustment factor for mortality, the baseline economic scenario, as described in Appendix 1.E of VM-20.

   b. \( b \) = the largest adjusted scenario reserve described in Paragraph 7.C.2.b below under any of the alternate economic scenarios described in Appendix 1.E of VM-20 under 95%[-105%] of anticipated experience mortality excluding margins. Because mortality variability may differ by company, if the magnitude of the company’s margin for mortality exceeds 5%, the company shall use the baseline mortality and the mortality augmented by plus and minus the company’s margin for this exercise.

Guidance Note: Note that the numerator should be the largest adjusted scenario reserve for the scenarios other than the baseline economic scenario, minus the adjusted scenario reserve for the baseline economic scenario, and 100% as the adjustment factor for mortality. This is not necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100% as the adjustment factor for mortality, or the absolute value of the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100% as the adjustment factor for mortality, both of which could lead to an incorrect test result.
There are 47 (=16x3-1) combined economic and mortality scenarios that should be compared for the determination of \( b \).

2. In calculating the ratio in subsection (Section 7.C.1) above:

a. The company shall calculate an adjusted scenario reserve for the group of contracts for each of the 16 economic scenarios using the three levels of mortality adjustment factors that is equal to either (i) or (ii) below:

i. The scenario reserve defined in Section 4, but with the following differences:
   a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph Section 7.C.1.b of this section.
   b) Using the interest rates and equity return assumptions specific to each scenario.
   c) Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.
   d) Shall reflect future mortality improvement in line with anticipated experience assumptions.
   e) Shall not reflect correlation between longevity and economic risks.

ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:
   a) Using the interest rates and equity return assumptions specific to each scenario.
   b) Using the mortality scalars described in Paragraph Section 7.C.1.b of this section.
   c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current available baseline economic scenario and the 15 other economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.
e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the stochastic exclusion ratio test unless it only a pre-reinsurance ceded single basis upon determining the either pre-reinsurance-ceded basis upon determining the pre-or post-reinsurance reserve-ceded aggregate reserves.

If the ratio calculated in this section is less than [x]% pre-non-proportional reinsurance, but is greater than [x]% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

iii. So, if SERT_{pre} \leq [x]% but SERT_{post} > [x]%, then compute the largest percent increase in reserve (LPIR) = (b-a)/a, both “gross of non-proportional” and “net of non-proportional.”

\[
LPIR_{pre} = \frac{(b_a - b_{an})/a_a}{b_a/a_a}
\]

\[
LPIR_{post} = \frac{(b_a - b_{an})/a_a}{b_{an}/a_{an}}
\]

Note that the scenario underlying b_{an} could be different from the scenario underlying b_{a}.

If SERT_{pre} \times LPIR_{pre}/LPIR_{post} \leq [x]%, then the block of contracts passes the SERT.

b. Another more qualitative approach is to calculate the adjusted scenario reserves for the 48 combined economic and mortality scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.
4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section or Section 7.D.2.b and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve (SR) requirements using the methodology in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

   a. The demonstration shall provide a reasonable assurance that if the stochastic reserve (SR) was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve (SR) exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would likely to change the conclusion to exclude the group of contracts from the stochastic reserve (SR) requirements.

   b. If, as of the end of any calendar year, the company determines the aggregate statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.

   c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an explanation of why the use of such a date will not produce a material change in the outcome, as compared to results based on an analysis as of the valuation date.

   d. The demonstration shall provide an effective evaluation of the residual risk exposure remaining after risk mitigation techniques, such as derivative programs and reinsurance.

2. The company may use one of the following or another method acceptable to the insurance commissioner to demonstrate compliance with subsection Section 7.D.1 above:

   a. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve calculated on a stand-alone basis.

   b. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the scenario reserve that results from each of a sufficient number of adverse deterministic scenarios.
c. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve SR calculated on a stand-alone basis, but using a representative sample of contracts in the stochastic reserve SR calculations.

d. Demonstrate that any risk characteristics that would otherwise cause the stochastic reserve SR calculated on a stand-alone basis to exceed the statutory reserve calculated in accordance with VM-A and VM-C, are not present or have been substantially eliminated through actions such as hedging, investment strategy, reinsurance or passing the risk on to the contract policyholder by contract provision.

E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve SR for a group of contracts using a single deterministic economic scenario, subject to the following conditions.
   a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies, contracts and certificates. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recurring premium payments, and guaranteed living benefits.
   b. The company certifies that the group of policies, contracts and certificates is not supported by a reinvestment strategy that contains future hedge purchases.
   c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing and the scenario reserve volatility across various company must pass the SERT when considering only the 16 economic scenarios, paired with the 100% mortality scenario.
   d. The company must disclose a description of contracts and associated features in the certification.

2. The stochastic reserve SR for the group of contracts under the Deterministic Certification Option is determined as follows:
   a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).
   b. The stochastic reserve SR equals the scenario reserve following the requirements for Section 4.
Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.

Commented [X269]: Recommend deleting guidance note, as it doesn’t provide full or clear scope of what may be excluded, so could be misread to either guarantee option for certain products or exclude the option for other products.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Non-Index Credit Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company only hedges index credits. If the company clearly separates index credit hedging from other hedging, then only the section only pertains to the other hedging if the index hedging follows. In those situations, the modeling of hedges supporting index credits can be simplified. In applying an index credit hedge margin, following the requirements in Section 4.A.A.1.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company shall be included in the calculation of the stochastic reserve, determined in accordance with Section 3.D and Section 4.D.

3. The company shall take into account the costs and benefits of hedge positions expected to be held by the company in the future along each scenario. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than [6] months, including the hedging strategy, used to implement the investment policy/strategy.

4. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. Also referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which is also referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

5. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve, otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserve otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserve needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserve attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock-tested.

Guidance Note: No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

C. Calculation of Stochastic ReserveSR (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no future hedge purchases, except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.1.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserveSR is given by:

\[ \text{Stochastic ReserveSR} = \text{CTE70 (best efforts)} + E \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}] \]
4. The company shall specify a value for E (the “error factor”) in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of E. The value of E may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, E must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recently available relevant period of data (but no less than 12 months), to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for E.

6. Such a back-test shall involve one of the following analyses:

a. For companies that model hedge cash flows directly (“explicit method”), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses – both realized and unrealized – observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g., reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

   To support the choice of a low value of E, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of E by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an “implicit method” or “cost of reinsurance method”), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

   i. Determine the hedge asset gains and losses—both realized and unrealized—incurred over the month attributable to equity, interest rate, and implied volatility movements.

   ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).
iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.

iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with less than 6 months of history, E should be at least 1.0.50. However, E may be lower than 1.0.50 if at least 6 months of reliable experience is available and/or if the change in strategy is a minor refinement rather than a substantial change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).
8. The company shall set the value of E reflecting the extent to which the future hedging program is clearly defined. To support a value of E below 1.0, there should be very robust documentation outlining the future hedging program. To the extent that documentation outlining the future hedging program is incomplete, the value of E shall be increased. Any increases required to the value of E to reflect that documentation is not available to support that the future hedging program is clearly defined shall be in addition to increases to the value of E to reflect a lack of historical experience or to reflect the back-testing results.

E. Additional Considerations for CTE70 (best efforts)

If the company is following a CDHS, the fair value of the portfolio of contracts falling within the scope of these requirements shall be computed and compared to the CTE70 (best efforts) and CTE70 (adjusted). If the CTE70 (best efforts) is below both the fair value and CTE70 (adjusted), the company should be prepared to explain why that result is reasonable.

For the purposes of this analysis, the SR and fair value calculations shall be done without requiring the scenario reserve for any given scenario to be equal to or in excess of the cash surrender value in aggregate for the group of contracts modeled in the projection.

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for purposes of reducing the stochastic reserve (SR), the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions if there has been a change to the hedge program.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., > 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily 100% for material changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy).

- An increase in the error factor may not always be needed for minor refinements to the hedge strategy (e.g., moving from swaps to Treasury futures).

Commented [CD287]: Not sure why this section is being deleted? Perhaps references to CDHS could be deleted, but otherwise this section still seems applicable.

Commented [CD286]: Reinstate this disclosure item, which is a rough reasonability check for regulator review/information on the modeled hedge benefit and can prompt further discussion.

Commented [X286]: Work is being done by the hedging DG. This is a placeholder. Need to reflect how clearly defined and well documented the hedge program is, to be able to rely on the backtesting provided. To the extent that hedge programs are not clearly defined, E should be increased to reflect that the backtesting cannot be relied on as an indicator of future effectiveness.

Commented [X285]: Perhaps references to CDHS could be deleted, but otherwise this section still seems applicable.
on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or adverse estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited to, a hedging strategy where material hedging assets will be obtained when the fixed indexed annuity and other in-scope products account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the variable fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets. There may be scenarios that are particularly costly to discontinuous hedging strategies, especially where those result in large discontinuous changes in sensitivities (Greeks) associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve $SR$, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve $SR$ otherwise calculated.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the reserves level. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B and Section 12.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may or may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more material behavior assumptions, if relevant to the risks in the product, and thus the approach will not undervalue the reserve.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the company qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Account transfers.
- Future deposits.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently (but no less than every 3 years) when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
   b. Surrenders.
   c. Partial withdrawals (systematic and elective).
   d. Account transfers (switching/exchanges).
   e. Resets/ratchets of the guaranteed amounts (automatic and elective).
   f. Future deposits.
   g. Income start date for the benefit utilization.
   h. Commutation of benefit (from periodic payment to lump sum) or vice versa.

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions. For example:
   a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing, ) or if the contract provisions incentivize the contract holders to transfer between accounts.
   b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).
   c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

Guidance Note: For some non-elective benefits (nursing home benefits for example), unless relevant company experience exists to the contrary, the use of incidence rates greater than zero after the surrender charge has ended, or the cash value has depleted might be inappropriate may not be prudent since it would reduce the modeled reserve.

Commented [X303]: Clarification
Commented [X304]: clarification
Commented [CD305]: delete this word

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.
4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):
   a. Gender.
   b. Attained age.
   c. Issue age.
   d. Contract duration.
   e. Time to maturity.
   f. Tax status.
   g. Account value.
   h. Interest credited (current and guaranteed).
   i. Available indices.
   j. Guaranteed benefit amounts.
   k. Surrender charges, transaction fees or other contract charges.
   l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100%...
efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., the non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holderstochastically modeled.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practicalityallowance for appropriate simplifications, approximations and modeling efficiency techniques, the use of dynamic models is encouraged, but not mandatory. Static assumptionsRisk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers), may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of behavior consistent with the economic scenarios and other variables in the model, including the non-scenario tested assumptions. The company shall test the sensitivity of results to understand the materiality of making alternate assumptions and follow the guidance discussed above on setting assumptions for sensitive behaviors.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution). To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the model) in order to determine exactly which scenario results are included in the CTE measure. Rather, in light of the products being valued, the company should be mindful of the general characteristics of those scenarios likely to represent the tail of the loss distribution and consequently use prudent estimate assumptions for behavior that are reasonable and appropriate in such scenarios. For non-variablefixed annuities, these “valuation” scenarios would typically display one or more of the following attributes:
   a. Declining, increasing and/or volatile index values, where applicable.
   b. Price gaps and/or liquidity constraints.
   c. Rapidly changing Volatile interest rates or persistently low interest rates.
   d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions.

Commented [X310]: Recommend replacing “dynamic” with “stochastic.” Risk factors with dynamic assumptions still need margins (although for an assumption that was part fixed and part dynamic, only one piece may have the margin but still the risk factor would have a margin).

Commented [X311]: Suggest replacing “Risk factors that are not scenario tested but” with “Static assumptions that” to improve clarity in the wording.

Commented [X312]: Get rid of some of the vague adjectives and be consistent with VM framework for simplifications.

Commented [CD313]: “non-variable”?

Commented [X314]: Editorial clarification to cover scenarios for all products/guarantees in scope.

Commented [X315]: Editorial for consistency with (a) above.

Commented [X316]: Suggesting deleting as we are not aware of dynamic credit spreads typically being modeled.
a. Remain logically and internally consistent across the scenarios tested.

b. Represent plausible outcomes.

c. Lead to appropriate, but not excessive, asset requirements.

4. The company should remember that the continuum of "plausibility" should not be confined or constrained to the outcomes and events exhibited by historic experience.

5. Companies should attempt to track experience for all assumptions that materially affect their risk profiles by collecting and maintaining the data required to conduct credible and meaningful studies of contract holder behavior.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:

   a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.

   b. Complies with the contract holder behavior requirements stated in Section 10.A to Section 10.G above in this section.

2. If the company models policy loans explicitly, the company shall:

   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.

   b. Assign loan balances either to exactly match each contract’s utilization or to reflect average utilization over a model segment or sub-segments if the results are materially similar.

   c. Model policy loan interest in a manner consistent with contract provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
Life Actuarial (A) Task Force 
8/8–9/22

I. Non-Guaranteed Elements

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy contract costs or values and are not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to non-variable fixed annuities include but are not limited to the following: fixed credited rates on fixed accounts, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollup rates, rollup period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.J.I.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of an NGE that:
   a. Is not based on some aspect of the policy or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

   However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude...
from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.

   a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve SR.

   b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve SR should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the maximum reserve, SR. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances). The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the maximum reserve, SR. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances).

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from similar industries or geographies that may be used to sub-divide inforce blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to...
B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2 for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

"How payout annuities vs. deferred annuities are distinguished."
i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:

\[ q_x^{20XX+n} = q_x^{20XX}(1 - G_{x+})^n \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage \((F_x)\) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual deferred annuities and deferred annuity contracts with guaranteed living benefits

\[ q_x^{2012+n} = q_x^{2012}(1 - G_{x+})^n \cdot F_x \]

b. [1983 Table “a”] for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_x^{1994+n} = q_x^{1994}(1 - AA_x)^n \]

iii. For a business segment with non-U.S. insureds, when little or no experience or information is available on a business segment, an established industry or national mortality table and mortality improvement scale may be used, with approval from the domiciliary commissioner.

4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

a. Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

b. Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by

</tr>
</tbody>
</table>
contract duration for an appropriate select period. As an alternative, if the company determines that mortality is affected by selection, the company could apply margins to the expected mortality in such a way that the actual mortality modeled does not depend on contract duration.

c. Modification and Relevance of Data

Even for a large company, the quantity of life exposures and deaths are such that a significant amount of smoothing may be required to determine expected mortality curves from mortality experience. Expected mortality curves, when applied to the recent historic exposures (e.g., three to seven years), should not result in an estimate of aggregate number of deaths less (greater) than the actual number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying data), older data may no longer be relevant. The “age” of the experience data used to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors that include, but are not limited to, trends in mortality experience, trends in exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative to mortality by amounts, changes in the mix of business and product features that could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience data used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves including margins for uncertainty with the mortality assumptions described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

Guidance Note: For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the industry mortality assumption described in Section 11.B.3 used in the blending.

2. Adjustment of Statutory Valuation Industry Mortality for Improvement

For purposes of the adjustment for credibility, the industry mortality table for a plus segment may be and the industry mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective industry mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.
b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.

f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve $SR$. If such an adjustment would reduce the stochastic reserve $SR$, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Other Guidance and Requirements for Assumptions

A. Overview

This section provides guidance and requirements in general for setting prudent estimate assumptions when determining either the SR or DR. It also provides specific guidance and requirements for expense assumptions.

B. General Assumption Requirements

1. The company shall use prudent estimate assumptions for risk factors that are not stochastically modeled by applying margins to the anticipated experience assumptions if such risk factors have been categorized as material risks by following Section 1.B Principle 3 and requirements in Section 12.C.

2. The company shall establish the prudent estimate assumptions for risk factors in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

3. The company shall model the following risk factors stochastically unless the company elects the stochastic modeling exclusion defined in Section 7:
   a. Interest rate movements (i.e., Treasury interest rate curves).
   b. Equity performance (e.g., Standard & Poor’s 500 index [S&P 500] returns and returns of other equity investments).

4. If the company elects to stochastically model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.

Guidance Note: It is expected that companies will not stochastically model risk factors other than the economic scenarios, such as contract holder behavior or mortality, until VM-22 has more specific guidance and requirements available. Companies shall discuss with domiciliary regulators if they wish to stochastically model other risk factors.

5. The company shall use its own experience, if relevant and credible, to establish an anticipated experience assumption for any risk factor. To the extent that company experience is not available or credible, the company may use industry experience or other data to establish the anticipated experience assumption, making modifications as needed to reflect the circumstances of the company.
   a. For risk factors (such as mortality) to which statistical credibility theory may be appropriately applied, the company shall establish anticipated experience assumptions for the risk factor by combining relevant company experience with industry experience data, tables or other applicable data in a manner that is consistent with credibility theory and accepted actuarial practice.
b. For risk factors (such as utilization of guaranteed living benefits) that do not lend themselves to the use of statistical credibility theory, and for risk factors (such as some of the lapse assumptions) to which statistical credibility theory can be appropriately applied but cannot currently be applied due to lack of industry data, the company shall establish anticipated experience assumptions in a manner that is consistent with accepted actuarial practice and that reflects any available relevant company experience, any available relevant industry experience, or any other experience data that are available and relevant. Such techniques include:

i. Adopting standard assumptions published by professional, industry or regulatory organizations to the extent they reflect any available relevant company experience or reasonable expectations.

ii. Applying factors to relevant industry experience tables or other relevant data to reflect any available relevant company experience and differences in expected experience from that underlying the base tables or data due to differences between the risk characteristics of the company experience and the risk characteristics of the experience underlying the base tables or data.

iii. Blending any available relevant company experience with any available relevant industry experience and/or other applicable data using weightings established in a manner that is consistent with accepted actuarial practice and that reflects the risk characteristics of the underlying contracts and/or company practices.

c. For risk factors that have limited or no experience or other applicable data to draw upon, the assumptions shall be established using sound actuarial judgment and the most relevant data available, if such data exists.

d. For any assumption that is set in accordance with the requirements of Section 12.B.5.c, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing and disclose the analysis performed to ensure that the assumption is set at the conservative end of the plausible range.

e. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

6. The company shall sensitivity test risk factors that are not stochastically modeled and examine the impact on the stochastic reserve. The company shall update the sensitivity tests periodically as appropriate. The company may update the tests less frequently, but no less than every 3 years, when the tests show less sensitivity of the stochastic reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company
may perform sensitivity testing:

a. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.

b. Using data from prior periods.

**Guidance Note:** Sensitivity testing every risk factor on an annual basis is not required. For some risk factors, it may be reasonable, in lieu of sensitivity testing, to employ statistical measures for margins, such as adding one or more standard deviations to the anticipated experience assumption.

7. The company shall vary the prudent estimate assumptions from scenario to scenario within the stochastic reserve calculation in an appropriate manner to reflect the scenario-dependent risks.

C. Assumption Margins

The company shall include margins to provide for adverse deviations and estimation error in the prudent estimate assumption for each risk factor that is not stochastically modeled or prescribed, subject to the following:

1. The level of margin applied to the anticipated experience assumptions may be determined in aggregate or independently as discussed in Section 1.B Principle 3. It is not permissible to set a margin less toward the conservative end of the spectrum to recognize, in whole or in part, implicit or prescribed margins that are present, or are believed to be present, in other risk factors.

   Risks that are stochastically modeled (e.g., interest rates, equity returns) or have prescribed margins or guardrails (e.g., assets, revenue sharing) shall be considered material risks. Other risks generally considered to be material include, but are not limited to, mortality, contract holder behavior, maintenance and overhead expenses, inflation and implied volatility. In some cases, the list of material risks may also include acquisition expenses, partial withdrawals, policy loans, annuitizations, account transfers and deposits, and/or option elections that contain an element of anti-selection.

2. The greater the uncertainty in the anticipated experience assumption, the larger the required margin, with the margin added or subtracted as needed to produce a larger Sr or DR than would otherwise result. For example, the company shall use a larger margin when:

   a. The experience data have less relevance or lower credibility.
   
   b. The experience data are of lower quality, such as incomplete, internally inconsistent or not current.
   
   c. There is doubt about the reliability of the anticipated experience assumption, such as, but not limited to, recent changes in circumstances or changes in company policies.
   
   d. There are constraints in the modeling that limit an effective reflection of the risk factor.
3. In complying with the sensitivity testing requirements in Section 12.B.6 above, greater analysis and more detailed justification are needed to determine the level of uncertainty when establishing margins for risk factors that produce greater sensitivity on the stochastic reserve.

4. A margin is permitted but not required for assumptions that do not represent material risks.

5. A margin should reflect the magnitude of fluctuations in historical experience of the company for the risk factor, as appropriate.

6. The company shall apply the method used to determine the margin consistently on each valuation date but is permitted to change the method from the prior year if the rationale for the change and the impact on the stochastic reserve is disclosed.

D. Expense Assumptions

1. General Prudent Estimate Expense Assumption Requirements

In determining prudent estimate expense assumptions, the company:

a. May spread certain information technology development costs and other capital expenditures over a reasonable number of years in accordance with accepted statutory accounting principles as defined in the Statements of Statutory Accounting Principles.

Guidance Note: Care should be taken with regard to the potential interaction with the inflation assumption below.

b. Shall assume that the company is a going concern.

c. Shall choose an appropriate expense basis that properly aligns the actual expense to the assumption. If values are not significant, they may be aggregated into a different base assumption.

Guidance Note: For example, death benefit expenses should be modeled with an expense assumption that is per death incurred.

d. Shall reflect the impact of inflation.

e. Shall not assume future expense improvements.

f. Shall not include assumptions for federal income taxes (and expenses paid to provide fraternal benefits in lieu of federal income taxes) and foreign income taxes.

g. Shall use assumptions that are consistent with other related assumptions.

h. Shall use fully allocated expenses.

Guidance Note: Expense assumptions should reflect the direct costs associated with the block of contracts being modeled, as well as indirect costs and overhead costs that have been allocated to the modeled contracts.

i. Shall allocate expenses using an allocation method that is consistent across
company lines of business. Such allocation must be determined in a manner that is within the range of actuarial practice and methodology and consistent with applicable ASOPs. Allocations may not be done for the purpose of decreasing the stochastic reserve.

j. Shall reflect expense efficiencies that are derived and realized from the combination of blocks of business due to a business acquisition or merger in the expense assumption only when any future costs associated with achieving the efficiencies are also recognized.

Guidance Note: For example, the combining of two similar blocks of business on the same administrative system may yield some expense savings on a per unit basis, but any future cost of the system conversion should also be considered in the final assumption. If all costs for the conversion are in the past, then there would be no future expenses to reflect in the valuation.

k. Shall reflect the direct costs associated with the contracts being modeled, as well as an appropriate portion of indirect costs and overhead (i.e., expense assumptions representing fully allocated expenses should be used), including expenses categorized in the annual statement as “taxes, licenses and fees” (Exhibit 3 of the annual statement) in the expense assumption.

l. Shall include acquisition expenses associated with business in force as of the valuation date and significant non-recurring expenses expected to be incurred after the valuation date in the expense assumption.

m. For contracts sold under a new policy form or due to entry into a new product line, the company shall use expense factors that are consistent with the expense factors used to determine anticipated experience assumptions for contracts from an existing block of mature contracts taking into account:

i. Any differences in the expected long-term expense levels between the block of new contacts and the block of mature contracts.

ii. That all expenses must be fully allocated as required under Section 12.D.1.h above.

2. Margins for Prudent Estimate Expense Assumptions

The company shall determine margins for expense assumptions following Section 12.C.
Section 13: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The allocation shall be made separately for DR and SR. The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

Table 12.1: Sample Allocation of Aggregate Reserve

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td></td>
<td>140</td>
</tr>
<tr>
<td>Allocation Basis for the excess of the Aggregate Reserve over the Cash Surrender Value Al: Max(Ri−Ci, 0)</td>
<td>10</td>
<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

| Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value | Li = (Ai)/ΣA*[Aggregate Reserve - 2Cj] |
|---|---|---|---|
| Li | 9.09 | 10.91 | 0.00 | 20 |
| Contract-level reserve Cj+ Li | 37.09 | 50.91 | 52.00 | 140.00 |

Option 2: Actuarial Present Value Approach

B. The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserveSR defined in Section 3.D.
   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows, as well as any cash flows that are scenario dependent.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.
   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserveSR defined in Section 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

   | Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value | Li = (Ai)/ΣA*[Aggregate Reserve - 2Cj] |
   |---|---|---|---|
   | Li | 9.09 | 10.91 | 0.00 | 20 |
   | Contract-level reserve Cj+ Li | 37.09 | 50.91 | 52.00 | 140.00 |

Commented [X367]: This method depends on the NAER, so would not work for companies that use direct iteration.

Commented [X368]: This could give an unstable allocation if there is an even mix of products with different risk profiles, so that the tail is populated with some scenarios where Product A does poorly and some where Product B does poorly. The single scenario will only reflect the riskiness of one of the products.

Commented [X369]: Not just the NAER, but the cashflows are also scenario dependent.

Commented [CD370]: "Section 3.D"

*Cash Surrender Value  
**Guaranteed Lifetime Withdrawal Benefit

**Guidance Note:** The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 1314: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section, and all contracts not passing the SET covered by Sections 1 through 13 of VM-22, are covered Section 14 of VM-22:
   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

Guidance Note: For Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f and Section 1314.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:
   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f, Section 1314.A.2.g or Section 1314.A.2.h, the...
company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 4414 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B) (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C) (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 4414.B.1.c above shall be made based on the materiality of the payments that are not substantially similar to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   **Guidance Note:** If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.
3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.

4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 1314 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*
   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.
   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

   Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5Y</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>90+</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>80–89</td>
<td>B</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>70–79</td>
<td>C</td>
<td>C</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>&lt; 70</td>
<td>D</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

2. **Premium Determination Dates**

a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d and A.2.e</td>
<td>Fixed payout annuities resulting from settlement options or annuitizations from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
<tr>
<td>A.2.g</td>
<td>Fixed income payment streams from CDAs, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
### Guidance Note:
For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

#### 2. Group Annuity and Related Certificates
| A.2.i | Group annuity and related certificates | Date consideration is determined and committed to by contract holder |

b. **Immaterial Change in Consideration**

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

3. **Statutory Maximum Valuation Interest Rate**

a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 1314.C.1) and its Premium Determination Date (Section 1314.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

b. **Statutory maximum valuation interest rates for jumbo contracts** are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

c. **Statutory maximum valuation interest rates for non-jumbo contracts** are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

d. **Quarterly Valuation Rate:**

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ I_q = R + S - D - E \]

Where:

a. R is the reference rate for that Valuation Rate Bucket (defined in Section 1314.C.4);

b. S is the spread rate for that Valuation Rate Bucket (defined in Section 1314.C.5);

c. D is the default cost rate for that Valuation Rate Bucket (defined in Section 1314.C.6);
and
d. \( E \) is the spread deduction defined as 0.25%.

e. **Daily Valuation Rate:**

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[
I_d = I_q + C_{d-1} - C_q
\]

Where:

a. \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b. \( C_{d-1} \) is the daily corporate rate (defined in Section 1314.C.7) for the business day immediately preceding the premium determination date; and

c. \( C_q \) is the average daily corporate rate (defined in Section 1314.C.8) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate \( (I_d) \) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4. **Reference Rate**

Reference rates are updated quarterly as described below:

a. The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b. Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c. The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

5. **Spread**

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a. Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.I) effective for the calendar year in which the premium determination date falls.

6. **Default costs** for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAML1C10C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAML2C10C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAML3C10C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAML4C10C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAML7C10C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAML8C10C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 1314.C.9.a].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating $I_q$ in Section 1314.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:
   
i. Bucket A:
   
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   
   b) Five-year certain only.

   ii. Bucket B:
   
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   
   b) 10-year certain only.

   iii. Bucket C:
   
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   
   c) 15-year certain only.

   iv. Bucket D:
   
   a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
   
   b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for
individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

   a) Column 1 of Table 4 is identical to column 1 of Table 1.
   b) Column 2 of Table 4 is 50% of column 2 of Table 1.
   c) Column 3 of Table 4 is identical to column 2 of Table 4.
   d) Column 4 of Table 4 is 50% of column 3 of Table 1.
   e) Column 5 of Table 4 is identical to column 4 of Table 4.
   f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 3.1.4.2.i), the following apply:

a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

Guidance Note: Under some group annuity contracts, certificates may be purchased on different
b. In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

**Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.
This page intentionally left blank
Valuation Manual Section II | Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for non-variable annuity contracts issued prior to 1/1/2024 are those requirements as found in Sections 1 through 13 of VM-22.

D. Minimum reserve requirements for non-variable annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 13 of VM-22.

The requirements in this section are still considered a part of PBR requirements and therefore are applicable to VM-G.

The below principles may serve as key considerations for assessing whether VM-21 or VM-22 requirements apply.

D. Minimum reserve requirements apply.

E. Index for index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for application of VM-22 requirements:

1. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereon, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.

2. Credits a rate of interest under the contract prior to the application of any market value adjustments that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

Minimum reserve requirements apply.

Commented [X373]: We believe a Fixed Annuity PBR Exemption should be incorporated into draft in a manner consistent with the Life PBR Exemption

Commented [VM22374R373]: Payon People: Proposed language to reflect small company exemption in place for life PBR (VM-20) to VM-22

Commented [CD375]: "non-variable annuity"?

Commented [CD377]: "non-variable annuity"

Commented [X376]: "Section 13 of VM-22" may need to be updated if it is decided to have separate chapters for VM-22 VIR and VM-22 PBR.

Commented [CD377]: "non-variable annuity"?

Commented [CD378]: Consider adding the sentence: "The minimum reserve requirements of VM-22 are considered PBR requirements for purposes of the Valuation Manual. This is so VM-G will apply to VM-22, which would be appropriate.

Commented [X379]: "Index-linked" annuity is not defined – only RILA and FIA in VM-22, recommend to revise the language or add a definition to define "index linked".

Commented [X380]: Recommend adding this part to E.1.b and delete the Guidance Note.
F. Index-linked or modified guaranteed annuity contracts or riders that do not satisfy either of the two conditions listed above criteria in Paragraph Section 2.E.1.i and Section 2.E.2 above and E.1.ii may be a key consideration for application of VM-21 are issued on 1/1/2024 and later are those requirements as found in VM-21.

Commented [X381]: VM-21 specifically says “These requirements do not apply to contracts falling under the scope of VM-A-255: Modified Guaranteed Annuities; however, they do apply to contracts listed above that include one or more subaccounts containing features similar in nature to those contained in modified guaranteed annuities (MGAs) (e.g., market value adjustments).” Is this a contradiction?

Commented [X382]: Consistent with E above.
Guidance Note: Policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraph C above including, but not limited to, Guaranteed Minimum Accumulation Benefits, Guaranteed Minimum Death Benefits, Guaranteed Minimum Income Benefits, Guaranteed Minimum Withdrawal Benefits, Guaranteed Lifetime Income Benefits, Guaranteed Lifetime Withdrawal Benefits, Guaranteed Payout Annuity Floors, Waiver of Surrender Charges, Return of Premium, Systematic Withdrawal Benefits under Required Minimum Distributions, and all similar guaranteed benefits shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.
2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.
3. After issuance, the base policy or contract value or benefits are determined by referencing the rider or supplemental benefit features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

E. If a term life insurance rider on the named insured[s] on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is

Commented [X383]: Still need the word “designs” otherwise this is saying the whole policy/contract was only created to disguise benefits, which would never be true.

Commented [X384]: This reference is another place where there would be a benefit distinguishing the PBR sections of VM-22 from the non-PBR sections.

Commented [X385]: These parallel requirements can be combined.
separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.

4.F. For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

4.G. Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve (for VM-20 and VM-22) or TAR (for VM-21) if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves (for VM-20 and VM-22) or reserves and TAR (for VM-21) using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.

Commented [X386]: Simplifications are judged relative to reserves for VM-20/VM-21 and TAR for VM-21.

Commented [X387]: This section states that “When advantageous, policyholders will commence living benefit payouts if not started yet.” This text seems to directly contradict VM-22 Section 6.H.2 which states “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally”. We suggest revising 6.H.2 to align with the text of 10.D.8.
See Equitable comment letter: supports full aggregation, but if choosing between the two exposed options for two 
reserving categories, prefers option 2.

suggest swapping the order of this section. That is, start with the "in scope" list, rather than the "out of scope" list.

Also, it seems like there should be specific mentions of GMDBs and GLBs, as there are in VM-21, since those 
guarantees can also be found on FIAs.

This needs to be revised to be in line with VM-21 Section 2.A. Consider removing "such as" list and adding a cross-
reference to VM-21 Section 2.A.

should this be "Non-Variable Annuity"? Otherwise, should "Fixed Annuity" be defined in the Definitions section?

We suggest moving or deleting the sentence “The company may elect to exclude one or more groups of 
contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test 
requirements defined in Section 3.E of VM-22.” from this section as it does not seem fitting here.

Does this belong in Scope? Do these still follow the other VM-22 requirements (if the old VM-22 interest rate 
determinations are left in the same chapter as the VM-22 PBR requirements)?

It is normal to then list what requirements such excluded contracts would follow. However, the statement here is 
more problematic because you can be excluded from the SR but still subject to VM-22.

We still have a question about whether RBC factors are still at an appropriate level, if principles-based capital is not 
developed. Were they set assuming that this reserve was at a CTE(70) level in the first place, or were they 
dependent on the prior framework?

Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest 
rates should be broader, if even necessary. Suggest editing as:

“these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant 
to applicable requirements in VM-A, and VM-C, and with the statutory maximum valuation rate for immediate 
annuities specified in Section 13.”

| This is not in VM-20 and would substantially change the exclusion. The intent is not to allow you to group a block that has material interest rate risk with a larger block that is insensitive to interest rate risks and thereby pass. If
"aggregate" referred to potential compounding of interest rate, longevity, or asset risk then this could be redrafted to clearly call out a 4th category of risk due to a combination of the first three. However, I think this is already implicitly covered.

Page 33: [20] Commented [CD218]   CA DOI   12/30/2021 4:15:00 PM

Note, there is no insertion of "aggregate risk levels across" here, like there was above. (To be clear, I don't support adding it.)

The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met May 11, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Vincent Tsang (IL); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Yujie Huang (TX); Tomasz Serbinowski (UT); and Craig Chupp (VA).

1. Discussed Tier Two Comments on the Proposed VM-22 Framework

Mr. Slutsker reviewed the list of discussion topics (Attachment Twenty-Four-A). Mr. Tsang said the proposed VM-22 framework should be consistent with VM-21, Requirements for Principle-Based Reserves for Variable Annuities. He said VM-21 has a 5% minimum error on the hedging program breakage expense, so VM-22 should also set 5% as its minimum error even though the hedging for the fixed annuity is not as complex as the hedging for the variable annuity. He said that due to the availability of policyholder options, a minimum error equal to zero is almost impossible to justify. He said he would consider a minimum error other than 5% if the industry can present the supporting data. Brian Bayerle (American Council of Life Insurers—ACLI) said the VM-22 minimum error is applicable only to static hedges. He said the ACLI could provide an example of static hedges on vanilla payout annuities for which a zero minimum error is appropriate. He suggested separating static hedges from dynamic hedges to maintain alignment with VM-21. John Miller (American Academy of Actuaries—Academy) said the Academy supports the bifurcation of static and dynamic hedges. He said the Academy believes that the minimum error for static hedges should be close to zero. He suggested adding the minimum error to the issues considered during the VM-22 field test. The Subgroup agreed to have back testing of the minimum error over multiple years of issues with assorted product designs either provided by industry prior to the field test or included as part of the field test.

Brent Dooley (Academy) gave an overview of the Academy longevity reinsurance presentation (Attachment Twenty-Four-B). He noted that much of the longevity reinsurance business covers annuitants who live in other countries. He said the product is primarily purchased by pension plans attempting to reduce longevity risk exposure and insurance companies writing pension risk transfer (PRT) annuities. He explained that of the five categories of longevity reinsurance listed in the presentation, only indexed based longevity swaps are excluded from the scope of the proposed VM-22 framework. Mark Hutchinson (Academy) said longevity reinsurance does not fit neatly into the current statutory accounting and valuation guidance. However, he suggested that longevity reinsurance be considered to fall under the exclusion of “certain non-proportional reinsurance” as stated in the Life and Health Reinsurance Agreements Model Regulation (§791). Mr. Slutsker noted that there are aspects of the Academy presentation that should be shared with the Life Risk-Based Capital (E) Working Group and the Statutory Accounting Principles (E) Working Group. Mr. Bayerle said that the ACLI comment letter (Attachment Twenty-Four-C) asked why the definition of longevity reinsurance in the draft VM-22 framework excludes agreements that Statement of Statutory Accounting Principles (SSAP) No. 61R—Life, Deposit-Type and Accident and Health Insurance indicates should not be treated as reinsurance. Mr. Dooley said that longevity reinsurance was intentionally excluded. He said a note could be added to the draft to clarify the reasoning.

Ms. Eom said the New Jersey Department of Banking and Insurance (NJ DOBI) comment letter (Attachment Twenty-Four-D) was written with longevity reinsurance considered as a stand-alone product that is to be treated differently from traditional ceded or assumed reinsurance. She proposed a limitation that would prohibit a standard projection amount (SPA) reserve for an individual contract from being negative. She said that the
stochastic reserve (SR) for a product line would be allowed to have a negative reserve for an individual line of business, but the negative reserve would not be allowed to offset reserves for other lines of business when determining the aggregate VM-22 reserve. She agreed to draft language supporting the proposal. She noted that principle #2 of the proposed VM-22 framework already prohibits aggregation of different product lines.

Mr. Slutsker said the Texas Department of Insurance (TDI) commented that the VM-31, PBR Actuarial Report Requirements for Business Subject to a Principle-Based Valuation, disclosures should be made more granular, to separately cover fixed indexed annuities (FIAs), fixed deferred annuities (FDAs), single premium immediate annuities (SPIAs), deferred income annuities (DIAs), PRT, guaranteed living benefits (GLBs), and non-GLBs. Ms. Eom said longevity reinsurance should also be included. She said that if longevity reinsurance is included with PRT, a note to that effect should be included in VM-22. Mr. Chupp said that he would prefer to have the VM-22 level of granularity match the granularity required for VM-20, Requirements for Principle-Based Reserves for Life Products. He noted that with a higher level of granularity, there is a risk that new products may not fit into an existing category. Mr. Carmello and several other Subgroup members said that it is important to get as much product information as possible.

Having no further business, the VM-22 (A) Subgroup adjourned.

Annuity Reserves & Capital Work Group
Presentation on
Longevity Reinsurance/Swaps: A Primer

Goals for today’s discussion

- Provide an overview of the major product designs in the market today.
- Discuss the key features and similarities/differences among the designs
- Provide input regarding which types of longevity reinsurance/swaps should be in-scope for VM-22 principle-based reserving (PBR)
  and discuss statutory considerations unique to these products

Who buys longevity reinsurance / swaps?

- Pension plans who want to reduce exposure to longevity risk; access reinsurance market through captives or insurance intermediaries
- Insurance carriers who write pension risk transfer (PRT) group annuities or individual payout annuities looking to manage risk and/or optimize capital
- Public announcements of transactions are the primary source of market data, with tens of billions of disclosed each year, denominated in a variety of currencies
- Markets with large, publicly-disclosed transactions include the U.S., U.K., Netherlands, and Canada

Wide variety of product designs exist in the market, and nomenclature is not standardized

- Most contracts are bespoke, and underwriting is typically facultative
- Many executed transactions and terms are not publicly disclosed

Other Statutory Accounting and Valuation Considerations

- Longevity Reinsurance doesn’t fit neatly into existing statutory accounting and valuation guidance
  - Not specifically contemplated by Statement of Statutory Accounting Principles (SSAP) 50, SSAP 61R, or model laws (MDL) 791/Appendix A-791
  - Agreements may be either temporary or permanent and may be either proportional or non-proportional
  - In some cases, only a single risk is reinsured from the underlying direct contract, which contains multiple risks
- How should ceding companies calculate reinsurance credit? Should assuming companies use the commissioners’ reserve valuation method (CRVM) or the commissioners’ annuity reserve valuation method (CARVM)?
- MDL 791 requires transfer of ALL defined risks (i.e. Credit, Reinvestment, Mortality) for Immediate Annuities to receive statutory credit for reinsurance
  - Scope excludes only YRT, assumption reinsurance, and “certain nonproportional reinsurance such as stop-loss or catastrophe reinsurance”
  - MDL 791 original intent: “improper…to enter into reinsurance agreements for the principal purpose of producing significant surplus aid for the ceding insurer, typically on a temporary basis, while not transferring all of the significant risks inherent in the business being reinsured”
  - Unclear under VM-30/AAT whether to allow projection of proportional reinsurance without meeting statutory risk transfer requirements
- For assuming companies, how should the “fee leg” of these transactions be treated?
  - Guaranteed future fees are available to fund unfavorable future longevity experience.
  - How should VM-22 requirements coordinate with RBC C-2 requirements to properly reflect the net retained longevity risk?
- How does one treat the “tail mortality risk” to which some of these designs are sensitive? Should stochastic mortality modeling be required?
  - For Non-Proportional Reinsurance, SSAP 61R paragraph 38 says to review “present value of expected recoveries using realistic assumptions”.

© 2022 National Association of Insurance Commissioners
Designing a Classical Longevity Reinsurance agreement starts by projecting out the future expected benefit payments, similar to a pension risk transfer deal.
Classical Longevity Reinsurance decomposes the projected benefit payments into the underlying longevity and asset risks, with the goal of transferring only the longevity risks.

Illustration is a permanent, “at-the-money” deal. Other forms exist.

Instead of being directly tied to a pool of annuitants, indexed-based longevity swaps are designed to transfer longevity risk in a more simplified manner, with a greater degree of basis risk.

November 19, 2021  

Mr. Bruce Sartain  
Chair, NAIC Valuation Manual (VM)-22 (A) Subgroup (Subgroup)  

Re: ACLI Comments on ARCWG VM-22 Framework Draft Proposal  

Dear Mr. Sartain:  

The American Council of Life Insurers (ACLI) appreciates the opportunity to provide comments on the American Academy of Actuaries (the Academy) Annuity Reserves and Capital Work Group VM-22 Framework Exposure.  

ACLI appreciates all the hard work of the Subgroup and ARCWG in development of this draft. We believe the framework is an excellent first step towards principles-based requirements for fixed annuities. We look forward to working with the Subgroup and ARCWG in further development of the framework, and on notable areas that were not addressed in this first exposure.  

ACLI supports the continued development of principles-based reserving. We believe that this development is the natural progression of measurement of underlying risks in company portfolios. PBR enables better measurement of complex guarantees and other risks and reflects the underlying experience of the block, while maintaining appropriate flexibility consistent with the complexity of the risks being measured.  

Our comments are broken into two sections: priority areas for requested comment and comments on individual sections of the VM-22. You will also find our comments in the accompanying Word document.  

VM-22 Exposure Comments and Priorities Comments:  

- Standard Projection Amount (SPA): If any reserve method includes a SPA, the ACLI supports making the SPA a nonbinding disclosure item across the applicable VM chapters. We appreciate the use of the SPA to help identify outlier assumptions; however, we note that having one-size-fits-all prescribed assumptions is extremely challenging due to the variety of designs in the market. Further, a binding floor introduces non-economic considerations to the reserve that do not align with management of the portfolio. Consistent with our feedback regarding the variable annuity framework, we are concerned
about the possibility of this approach producing false positives and false negatives regarding outliers.

- **Reserving Categories:** We believe aggregation should be consistent with management of liabilities and assets throughout the lifecycle of the portfolio and VM-22 should allow for companies to designate aggregation of blocks consistent with their operational and investment management. Multiple categories and other aggregation limits could create disconnects with the actual management and asset portfolio of the company. Further, a greater level of aggregation encourages well-diversified portfolios and sound-risk management.

  Were multiple reserve categories to be defined, we would support a principles-based categorization to accommodating innovation in the market. Further, we suggest an “at issue” approach to better align with management of the block and to avoid any disconnects in the level of the reserve were a block to switch between categories. Additionally, certain additional disclosures may not be applicable under this approach, such as those related to investment strategy when the company is not modeling it; we would suggest limiting the disclosures and reporting to items actually used in the calculation. For Option 1, we suggest deleting item #6 to be consistent with VM-21 or at least need to exclude payment streams from VAs which are scoped into VM-21.

- **Model Segments (Section 3.E):** Consistent with our comments on reserving categories, we believe the model segments should appropriately align with the internal management framework of companies to appropriately reflect inherent offsets in risks, which is in the spirit of a principle-based framework. We do not believe restrictive requirements around segments serves to solve any known problems, as two disjoint scenarios cannot occur at the same time within a company’s portfolio. We suggest consistency of this text with the existing VM-20 Section 7.A.1.b.

- **Allocation (Section 12):** We believe discussion of allocation of aggregate reserves should be analyzed as part of the field study.

- **VM-21 vs. VM-22 Distinction (VM Section II edits):** Consistent with the exposed framework, we support the continued inclusion of RILA and RILA-like products within VM-21. We are appreciative of the key considerations outlined in Valuation Manual Section II. Reserve Requirements Subsection 2.E and support further clarification of the intent of this text for greater clarity on the applicable guidance.

- **Exclusion Test:** ACLI is supportive of the exclusion test, however, we believe there are areas that could be clarified. We think there could be greater clarity regarding how exactly the exclusion test should be executed. For the Deterministic Certification Option, we request the text to be clarified regarding what business can use this option due to potential confusion in the current text; it would be clearer if the Guidance Note after 7.E.2 were moved to the beginning of Section 7.E to clarify what type of business falls into this category.
We do not believe in the necessity of including longevity risk within the scope of the exclusion test since we are not attempting to model longevity/mortality stochastically. We recommend striking longevity risk related components of this section throughout, including in 7.B and 7.C.1, and deleting the Drafting Note after 7.E.1.d.

Please find additional comments below in Section 7.

**Specific feedback on sections:**

- **Section 1**
  - A (Purpose): The proposal suggests VM-22 is not operative until 1/1/2024, which contradicts Section 13 and existing requirements. We would suggest rewording this to clarify that Section 13 is effective after 12/31/2017. Further, we would suggest consistency in labeling of dates (either all text or all numeric).
  - A (Relationship to RBC Requirements): The VM-21 guidance note was not included in VM-22; however, we believe it would be appropriate to retain and reword to say, “products that calculate a stochastic reserve”, since the relationship to RBC would likely be maintained.
  - B (Principles): We would support consistent application of principles across all chapters as currently VM-20 does not have a like-set of principles. We believe this could involve a broader discussion of the assorted product requirements in the VM. As a shorter-term fix, we would recommend generalizing the principles where appropriate and moving these to "Section I. Introduction" or "VM-01" and equally applying to VM-20.
  - B (Principle 2): We support this principle but note that later sections appear to contradict this principle. For example, the statement “The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario.” contradicts with the introduction of additional reserve categories and other limitations (such as model segment restrictions).
  - B (Principle 3): We suggest deleting the sentence “Generally, assumptions are...” since it does not provide guidance. We also suggest tightening the remainder of the text for clarity.
  - B (Principle 5): We recommend deleting the third sentence (starting with “Therefore, the use of assumptions...”) because this lacks historical context and is covered by the final sentence.
  - C (Risks Reflected): Consistent with our comments on 1.B, we would support consistent application of risks reflected across all chapters, rather than embedding the language in each chapter. Were this to be retained in VM-22, we would suggest maintaining consistency with VM-21 to avoid any confusion.
  - C.2.c.i: We recommend removing the bullet “Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above” as this is unclear and probably extraneous.
  - C.3: We recommend removing this section. With the specific RBC language removed, the section loses meaning: "a" is unnecessary and "b" is redundant with
other sections of the VM which allow for materiality considerations (language in VM-20 is likely better for this purpose and should be used consistently).

- C.4.b.iv: We recommend removing the bullet “Significant future reserve increases as an unfavorable scenario is realized” as this is extraneous.

- C.4.c (General business risks): List could be expanded to include operational risk and litigation risk.

- D (Specific definitions for VM-22): It seems the definitions included in this section are largely only used for the purpose of establishing the Scope in Section 2. Since this is intended to be a principles-based methodology, recommend a strong definition of “Fixed Annuity” instead of specific products underneath this business. The first paragraph in A. Scope seems to provide this with specific references which are out of scope. If changing the scope section, we would suggest deleting the various product definitions if not used elsewhere; if these definitions are potentially applied beyond VM-22, we would suggest moving any necessary definitions to VM-01.

- D (Deferred Income Annuity (DIA) definition/Single Premium Immediate Annuity (SPIA) definition): Suggest aligning the cut-off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1-year that currently is in the VM-22 draft.

- D (Fixed Indexed Annuity (FIA) definition): Is “typically” intended to be a requirement in the definition? That is, to qualify as FIA does there need to be guaranteed principle?

- D (Index Parameter definition): We would suggest adding performance trigger to the list, along with other potential crediting methods; alternatively, the definition could specify that the crediting methods listed are examples only.

- D (Longevity Reinsurance definition): The definition states that “Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition”. Why is this the case and does this imply that longevity swaps are not within the scope of VM-22? Recommend adding to the out-of-scope list in “2.A. Scope” if that is the case. Clarification would also be helpful on what guidance should be used for these agreements if out of scope for VM-22. Further, we would suggest removing “typically” from the definition.

- D (Modified Guaranteed Annuity): We recommend editing the definition as follows “A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account…”

- D (Pension Risk Transfer (PRT) Annuity definition): Is “typically” intended to be a requirement in the definition? That is, to qualify as PRT must the insurance company have the asset risk? Consistent with the comment on Longevity Reinsurance, it would be helpful to clarify where a longevity swap contract falls within these definitions. Notably, index-based longevity swaps should be out of scope as they do not meet definition of “annuity contract” in SSAP 50. It should also be made explicit that PRT contracts can include lump sum benefits, death benefits and cash balance benefits as well.

- D (Registered Index-Linked Annuity (RILA)): It is unclear to us why RILA is defined in VM-22 when it is being used to exclude the product from VM-22 requirements.
o D (Structured Settlement Contracts (SSC)): Suggest striking sentence “Adverse mortality is typically expected for these contracts.” from definition. Additionally, it is possible that there may be non-substandard settlements.

- **Section 2**
  - Consistent with our comment in Section 1, the language around effective date should be clear this only applies to new PBR methodology, and rates in Section 13 have a different effective date.
  - We would support reworking this section to rely on principles, rather than definitions to determine what is in and out of scope. As product innovation continues, a simple list may not appropriately accommodate the applicability of this chapter. However, if such a list is included, then we believe it should align with the full list presented in Section 13.
  - We suggest moving or deleting the sentence “The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.” from this section as it does not seem fitting here.

- **Section 3**
  - B: Guidance is needed on how a pre-reinsurance reserve is to be determined.
  - D: The term "Deterministic Certification Option" may be confusing, as there is no "deterministic" reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the phrasing to "with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E."*
  - E.1: Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest rates should be broader, if even necessary. Suggest editing as:
    
    “these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A, and VM-C, and with the statutory maximum valuation rate for immediate annuities specified in Section 13.”
  - E.2: This section seems to indicate that the grouping of contracts in exclusion testing should be the same as the grouping of contracts for aggregation. This might cause fewer product types to be qualifying for exclusion if the test must be performed at a higher level of aggregation.
  - E (Guidance note beginning "The intention of contracts that pass the stochastic exclusion test...’): We believe this guidance note is unnecessary as the intent of the section is clear, and the wording is possibly confusing.
  - F (Allocation) Either in this item or in Section 12 allocation to contracts not covered by PBR methodology in VM-22 needs to be addressed e.g., carve out because reserves calculated on seriatim formulaic basis.
  - G (Prudent Estimate Assumptions): This sub-section seems more appropriate in Section 4 (or pulled out completely and consolidated within "I. Introduction" or "VM-01" and applied to all PBR methods).
G.2: Suggest replacing “If the results of statistical testing or other testing” with “If the results of the review” to simplify language and avoid possible confusion.

Section 4

A.1.b (Guidance Note): The purpose of this guidance note is not clear as these charges would be reflected in the cash flows.

A.2: Suggest editing the first sentence to note scope is FiAs and to avoid confusion regarding the term “investment guideline” as follows: “Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy.”

Given that Section 9 covers hedging, we would suggest considering moving parts of Section 4.A.4 to that section.

A.4: Suggest rewording “Future hedging program” to “hedging program with future transactions” to avoid ambiguity.

A.4.b ii b: “Any other purpose” in the last sentence seems overly broad and should be narrowed.

A.4.b ii c: Margins are discussed in a different section, so recommend deleting.

A.4.b i c: We believe the company should determine the appropriate margin based on their demonstration of effectiveness. Any guardrails on these undetermined values should be minimal, including as low as 0, subject to the appropriate demonstration of effectiveness. Further, we believe that documentation of effective product management should be contemplated in addition to historical effectiveness.

A.5: Unclear why Revenue Sharing is considered for non-variable products, can probably delete.

B.1: Section does not specify what the reserve floor shall be (if any) for contracts without cash surrender value.

B.3.a We believe that assets held in the separate account with performance not impacting policyholder benefits should be modeled consistent with how the business is managed.

D.4.b: Request clarification around the meaning of “general account index funds.”

E.1.b: Suggest deleting “in contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.” as it appears to be covered by E.1.a.

E.2: Suggest deleting “may” as there appears to be only option.

Section 5: The wording and titling may need to be tightened due to clarify which items apply to assumed and ceded reinsurance in the text.

Section 7

B.3: We recommend removing “pension risk transfer business” from products scoped out of SET certification method. It is unclear why this business would be treated differently from individually issued business for testing intended to capture interest rate risk.
o C.1: As written, the SERT assumes a single premium product given the change of the denominator to the scenario reserve. Alternative product designs (such as longevity swap) could result in unintended results. We recommend maintaining consistency with VM-20 and using a denominator of future benefits (annuity payments, DBs, etc., excluding premium considerations, expenses, etc.).

o C.2.d: Clarification is needed around reference to “significantly different risk profiles.”

o C.3: We request clarification or definition of the term “non-proportional reinsurance.”

o C.3.a.iii: We believe subscript “gy” should be “gn.”

o D.1.a: Does this statement imply a floor reserve of VM-A and VM-C? VM-20 does require the NPR as the floor of the reserve but as written, VM-22 does not require a floor reserve. Recommend removing 1.a. Same statement with the 2.a statement demonstration. This requirement does not apply to the other permitted tests, which seemed counterintuitive.

- **Section 9**
  
  o Section 4.A.4 (Modeling of Hedges) has some relationship with this section, we request clarification around the applicability of these two areas of hedge guidance.

  o A.1: We seek clarification of this text: if a company only hedges indices or separates index crediting from other hedges, does this apply, or does it only apply to any other hedging?

  o A.3: The sentence “Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than [6] months.” seems to suggest you would do something other than the actual hedging strategy after [6] months. In this case, what are you assuming for modeling? We suggest clarification of this sentence.

  o D.2: Suggest replacing “indexed” with “fixed” since this would apply to all fixed annuities.

- **Section 10**

  o A.7: We would suggest rewording this section to be considerations rather than posed as questions.

  o D.8: This section states that “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally.” This text seems to directly contradict Section II. Reserve Requirements 6.H.2 which states “When advantageous, policyholders will commence living benefit payouts if not started yet.” We suggest revising 6.H.2 to align with the text of 10.D.8.

  o C (Sensitivity Testing): Suggest updating bullet to “Other material behavior assumptions if relevant to the risks in the product.”

  o E.2: Suggest replacing “Risk factors that are not scenario tested but” with “Static assumptions that” to improve clarity in the wording.

  o F.1.d (Volatile credit spreads): Suggesting deleting as we are not aware of dynamic credit spreads typically being modeled.
- **Section 11**
  - Specific requirements will require further discussion, particularly what if any industry experience is identified for the SPA. Ideally, updated, and appropriate assumptions should be used for better alignment and to avoid any false positives flagged as an outlier by the SPA.
  - A.4: Termining the segments “mortality (longevity) segments” would be easier to understand than “plus (minus) segments.”
  - B.3.i.c: For PRT an assumption based on a third-party data provider would be better than the industry table to get contract specific mortality assumptions. Is this permitted? The guidance note in A.3 seems to get at this, but it is not clear in B.3.i.c whether this is allowed. This is an important distinction as PRT population can vary from those populations the tables are based upon.
  - B.3.iii The phrase “When little or no experience or information is available on a business segment” is not included, unlike in (i) and (ii) of the same sub-section. It appears to be the intent that this is the only situation in which this would apply, but it would be helpful to make this explicit.
  - C.1: Both plan and industry data should get weighted for business such as PRT. This text says to blend with prescribed tables, but that might not make sense unless additional experience data was unavailable.
  - C.2: Mortality improvement should be consistent with the underlying tables used, so we would suggest this being based on available experience subject to appropriate guardrails.

- **Section 12**: We believe discussion of allocation of aggregate reserves should be analyzed as part of the field study.

- **Section II. Reserve Requirements**
  - We believe a Fixed Annuity PBR Exemption should be incorporated into draft in a manner consistent with the Life PBR Exemption.
  - 6.H.2: This section states that “When advantageous, policyholders will commence living benefit payouts if not started yet.” This text seems to directly contradict VM-22 Section 6.H.2 which states “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally”. We suggest revising 6.H.2 to align with the text of 10.D.8.

We appreciate the consideration of our comments and look forward to discussing at a future meeting.

Sincerely,

[Signature]

cc: Reggie Mazyck, NAIC
Dear Mr. Slutsker,

The New Jersey Department of Banking and Insurance (NJ DOBI) appreciates the opportunity to provide input to the VM-22 Subgroup regarding the currently exposed draft framework for VM-22. The purpose of this letter is to provide input related to the aggregation approach outlined in VM-22. Specifically, our comments relate to current Section 3.D.3.

We understand that there is current work underway regarding the appropriate approach for aggregation under VM-22, and the current language of subparagraph 3 states “The reserve may be determined in aggregate across various groups of contracts as a single model segment when determining the SR.” While we understand that under a principle-based framework there may be a desire to allow “credit” in the reserves for diversification across individual products or individual policies, we have some concern that full aggregation of all business in the scope of VM-22 may produce inappropriately low reserves. In some instances, products subject to VM-22 may involve future premium or fee revenue that exceeds future benefits, resulting in a negative reserve. If VM-22 indicates that all business may be aggregated, this could imply that certain blocks of business will have reserves that implicitly rely on the future premiums or fees associated with other blocks of business.

As an example, consider a company that has two blocks of business: traditional Single Premium Immediate Annuities (SPIAs) and Longevity Reinsurance (both of which are defined in VM-22). The reserves for the SPIAs would be based on the present value of future benefits and expenses, and a positive reserve would result under a principle-based calculation. For Longevity Reinsurance (which has periodic premium payments throughout the contract life), a principle-based calculation would likely produce a negative reserve, at least in early durations, since the present value of future premiums would exceed the present value of future benefits and expenses (assuming the product was appropriately priced). Under an aggregation approach across all lines of business, the positive SPIA reserves would be reduced by the Longevity Reinsurance negative reserve.

Under current statutory reserving approaches, negative reserves are avoided via the use of net premium approaches. For example, for annual premium whole life insurance, reserves are calculated using net premiums rather than gross premiums to avoid a negative reserve at issue. This net premium reserve approach was maintained as a floor in VM-20.

We strongly recommend a similar approach for Longevity Reinsurance and other products within VM-22 that may generate negative reserves. Rather than including all future premiums in the principle-based reserve calculation under VM-22, reserves should be calculated and floored using only the net premiums that are solved for at issues such that the starting reserve is no less than $0. This would serve to ensure that a negative reserve is not held on any product group, and then offset with positive reserves for other product groups.

If there is general agreement regarding such a modification, we would be happy to work with the VM-22 subgroup to draft specific language outlining this approach for inclusion in VM-22.
If you have any questions regarding this letter, please do not hesitate to contact me at
Seon-min Edm dobie ov.

Sincerely,

/\n

New Jersey Department of Banking and Insurance
The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met April 27, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Vincent Tsang (IL); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Yujie Huang (TX); Tomasz Serbinowski (UT); and Craig Chupp (VA).

1. Discussed Tier One Comments on the Proposed VM-22 Framework

Chris Conrad (American Academy of Actuaries—Academy) said the Academy comment letter (Attachment Twenty-Five-A) references a spreadsheet (Attachment Twenty-Five-B) that compares VM-22, Statutory Maximum Valuation Interest Rates for Income Annuities, net spreads to net spreads from VM-20, Requirements for Principle-Based Reserves for Life Products, and VM-21, Requirements for Principle-Based Reserves for Variable Annuities, in a high spread environment (3/31/2020) and a low spread environment (3/31/2021). He said the comparison shows that the yields are not dramatically different. He said the takeaway is that there is a lot of conservatism in the baseline defaults that have been subtracted to get the net spreads. He noted that the VM-22 credit quality distribution adds conservatism by not considering private placements, commercial mortgages, structured securities, and below-investment-grade bonds in the rate determination. He said the Academy recommends using the VM-22 credit quality distribution as the investment guardrail. Mr. Carmello said he favors the VM-20 approach and does not support using the VM-22 credit quality distribution. Ms. Eom said she would like to wait to see field test results showing how reserve calculations using the VM-22 credit quality are affected by the current economic environment. Several Subgroup members concurred with Ms. Eom. Mr. Tsang said the Subgroup should determine the credit quality distribution prior to initiating the field test. Brian Bayerle (American Council of Life Insurers—ACLI) said the ACLI favors a credit quality distribution that better reflects companies’ existing portfolios.

Mr. Slutsker reviewed the comments submitted by the Texas Department of Insurance (TDI), the California Office of Principle-Based Reserving (OPBR), and the ACLI on the proposed VM-22 revisions document (Attachment Twenty-Five-C). He said the TDI is recommending that the credit quality distribution be set consistently for VM-20, VM-21, and VM-22 at 20% AA-rated bonds and 80% A-rated bonds. Steve Tizzoni (Equitable) said the Equitable comment letter (Attachment Twenty-Five-D) supports the current VM-22 credit quality distribution, which he believes is representative of an A or A- credit quality. He agreed that the approach proposed by the TDI would also be reasonable. Mr. Bayerle asked whether Subgroup members prefer having the same credit quality distribution for VM-20, VM-21, and VM-22 or continuing with separate credit quality distributions for each chapter. Ms. Lam said the California OPBR prefers having separate distributions for each chapter. Mr. Carmello said an argument could be made for having separate credit quality distributions for each product. Mr. Leung expressed the desire to have credit quality distributions differ by product reserving category. Mr. Bayerle said that separating by individual product or product reserving category would increase the complexity for companies. Mr. Leung asked if the Academy might be able to perform model office runs to generate the results for the different credit quality distributions. Mr. Conrad said the Academy, the ACLI, and the NAIC are jointly working to engage a consultant to lead the field test. He said the consultant’s task will include model office development. He added that it will be a while before any work results from that effort. Mr. Slutsker asked if it might be possible to use the Academy’s existing VM-21 model office to do preliminary testing. Mr. Conrad agreed to check. Mr. Slutsker noted that the majority of Subgroup members favor waiting until field test results are available before deciding on the credit quality distribution approach.
2. Discussed Tier Two Comments on Proposed VM-22 Framework

Mr. Bayerle said the ACLI believes that Valuation Manual chapters should share a consistent set of principles. He suggested that there should be a separate chapter in which core principles reside. Several Subgroup members agreed that there should be consistency across chapters. Mr. Boerner said the ACLI could develop a proposal for consistency across the chapters and submit it to the Life Actuarial (A) Task Force. He then said the Subgroup should be allowed to complete its work on the VM-22 proposal before attempting the consolidation of principles into a single chapter.

Mr. Slutsker discussed the TDI recommendation to add a general assumptions section to VM-22 to match similar sections in VM-20 and VM-21. Subgroup members agreed to adding a general assumptions section.

Mr. Slutsker said a TDI comment questioned whether a company should be allowed to retrospectively apply the proposed VM-22 requirements back to the beginning of the transition period. Mr. Leung said he is aware that some companies retrospectively applied VM-20 during its transition period. Ms. Lam said that VM-20 is silent on the question of retrospective application. She said that the California OPBR would want the company to get the approval of its domiciliary commissioner before retrospective application is allowed. The Subgroup agreed that the VM-22 proposal will be silent on retrospective application, with the expectation that any such request must receive domiciliary commissioner approval.

Ms. Lam said that the California OPBR wishes to reconsider its comment requesting early adoption of the proposed requirement. She said the comment considered that VM-21 allowed early adoption but given the Subgroup determination that the application of the proposed VM-22 requirements will be prospective only, early adoption is no longer warranted.

Mr. Slutsker said an ACLI comment asked about the determination of the minimum error on the new index credit hedging program breakage expense. Mr. Bayerle said the minimum error should be tied to the demonstration of the effectiveness of the hedge instrument, with a range as low as zero. Mr. Slutsker said one option is to include the issue in the field test. Mr. Tsang asked if the ACLI could provide data to support the zero minimum error level. Mr. Bayerle said the ACLI will work with companies to provide the support.

Mr. Bayerle said the ACLI proposes the optionality for some products to be exempted from the requirements of the proposed VM-22 requirements without having to pass an exclusion test. He identified the single premium immediate annuity as a product that should qualify for such an exemption.

Having no further business, the VM-22 (A) Subgroup adjourned.

https://Support Staff Hub/Member Meetings/2022 NAIC Meetings/Spring National Meeting/Committee Meetings/LIFE INS and ANNUITIES (A) COMMITTEE/Life Actuarial (A) TF/Summer LATF Calls/VM-22 Subgroup/04 27/4_27 VM-22 Minutes.docx
February 9, 2022

Ben Slutsker, Chair
Valuation Manual (VM)-22 (A) Subgroup
National Association of Insurance Commissioners (NAIC)

Dear Mr. Slutsker,

The American Academy of Actuaries1 Annuity Reserves and Capital Work Group (ARCWG) has recommended a reinvestment credit quality assumption consistent with the current VM-22 mix. The work group is recommending the VM-22 mix rather than the VM-20/VM-21 reinvestment mix because the VM-22 credit quality distribution is more representative of the actual investment practices of companies. Summarized below are the two different credit quality distributions:

- VM-20/VM-21: 50% AA, 50% A
- VM-22: 5% Treasury, 15% AA, 40% A, 40% BBB (Note: weights are spread out over the three rating notches for non-Treasuries)

The work group thought it might be useful in regulator deliberations to provide an analysis of the difference in the credit spreads net of conditional tail expectation 70 (CTE70) default costs between the VM-20/VM-21 and VM-22 reinvestment mix credit quality assumptions. To this end, the work group created the accompanying spreadsheet showing the credit spreads net of CTE70 defaults for the two reinvestment assumptions for securities with weighted average lives (WALs) of two years, five years, 10 years, and 30 years. The analysis was performed at two points in time: March 31, 2020 (spreads were above the long-term average) and March 31, 2021 (spreads were below the long-term average). Recall that the work group has recommended consistency in methodology with VM-20 and VM-21, so the net spreads grade to the long-term assumptions by year four in both cases. Table A is a summary of the difference between net spreads of the VM-22 mix less net spreads of the VM-20/VM-21 mix:

---

1 The American Academy of Actuaries is a 19,500-member professional association whose mission is to serve the public and the U.S. actuarial profession. For more than 50 years, the Academy has assisted public policymakers on all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues. The Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.
Also note that the CTE70 default costs rise exponentially as credit quality decreases, significantly blunting the increase in net spreads (as Table A shows). This relationship is displayed in Table B for a 10-year WAL security.

Table A

That being said, fixed annuities rely on yields in the general account to a greater degree than many other products—e.g., variable annuities—meaning a small change in net spread can have a material impact on the reserve. Taking this into account, and due to the VM-22 distribution better reflecting actual industry investment practices of companies, the work group is recommending a reinvestment credit quality assumption consistent with the current VM-22 mix. We also note that this mix still has significant elements of conservatism, as it omits consideration of private placements, commercial mortgages, structured securities, and below-investment-grade bonds.

Please let us know if you have any follow-up inquiries in response to this analysis. Again, we appreciate the opportunity to present the fixed annuity framework and all of the efforts made by the NAIC VM-22 Subgroup to focus on this topic.

Sincerely,

Chris Conrad
Chairperson, Annuity Reserves and Capital Work Group
American Academy of Actuaries

VM-22 PBR: Requirements for Principle-Based Reserves for Non-Variable Annuities

Drafting Overview: This document is the ARCWG-proposed draft Valuation Manual wording for VM-22 PBR for non-variable annuities. The edits reflected in this draft are made in association with the recommendations in the Annuity Reserves Work Group-proposed VM-22 presentation, exposed by the VM-22 Subgroup in October 2020. Each section shows editorial mark-ups compared to existing VM-20 or VM-21 wording, which is included as a draft note at the beginning of each section (with the only exceptions being Sections 1 and 2 that do not contain mark-ups to existing Valuation Manual wording).

  A. Stochastic Exclusion Test Requirement Overview ................29
Section 1: Background

A. Purpose

These requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2024. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts, the Commissioners Reserve Valuation Method (CRVM).

**Guidance Note:** CRVM requirements apply to some group pension contracts.

B. Principles

The projection methodology used to calculate the stochastic reserve is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves.

**Guidance Note:** The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

**Principle 1:** The objective of the approach used to determine the stochastic reserve is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

**Principle 2:** The calculation of the stochastic reserve is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cash-flow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

**Principle 3:** The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the
stochastic reserve at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve, the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

Guidance Note: The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle.

Principle 4: While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

Principle 5: Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve. Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve without also reducing risk on scenarios similar to those used in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

C. Risks Reflected

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and
   b. Capable of materially affecting the reserve.

2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
      i. Credit risks (e.g., default or rating downgrades).

Commented [A5]: We suggest deleting the sentence "Generally, assumptions are..." since it does not provide guidance. We also suggest tightening the remainder of the text for clarity.

Commented [A6]: We recommend deleting the third sentence (starting with "Therefore, the use of assumptions...") because this lacks historical context and is covered by the final sentence.

Commented [A7]: Consistent with our comments on 1.B, we would support consistent application of risks reflected across all chapters, rather than embedding the language in each chapter. Were this to be retained in VM-22, we would suggest maintaining consistency with VM-21 to avoid any confusion.
ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).

iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).

iv. Performance of equities, real estate, and Schedule BA assets.

v. Call risk on callable assets.

vi. Separate account fund performance.

vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).

viii. Currency risk.

b. Liability risks

i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.

ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.

iii. Utilization risk associated with guaranteed living benefits.

iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.

v. Annuitization risks.

vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).

vii. Applicable expense risks, including fluctuation maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks

i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.

ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).

iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:

Commented [A8]: We recommend removing the bullet “Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above” as this is unclear and probably extraneous.

Commented [A9]: We recommend removing this section. With the specific RBC language removed, the section loses meaning: “a” is unnecessary and “b” is redundant with other sections of the VM which allow for materiality considerations (language in VM-20 is likely better for this purpose and should be used consistently).
a. Those not associated with the policies or contracts being valued, or their supporting assets.

b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:

a. Asset risks
   i. Liquidity risks associated with sudden and significant levels of withdrawals and surrenders.

b. Liability risks
   i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.
   ii. Catastrophic events (e.g., epidemics or terrorist events).
   iii. Major breakthroughs in life extension technology that have not yet fundamentally altered recently observed mortality experience.
   iv. Significant future reserve increases as an unfavorable scenario is realized.

c. General business risks
   i. Deterioration of reputation.
   ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.
   iii. Poor management performance.
   iv. The expense risks associated with fluctuating amounts of new business.
   v. Risks associated with future economic viability of the company.
   vi. Moral hazards.
   vii. Fraud and theft.

D. Specific Definitions for VM-22

Buffer Annuity
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

Deferred Income Annuity (DIA)
An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin one year or later after (or from) the issue date if the contract holder survives to a predetermined future age.

**Fixed Indexed Annuity (FIA)**
An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, typically with guaranteed principal.

**Flexible Premium Deferred Annuity (FPDA)**
An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

**Funding Agreement**
A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

**Guaranteed Investment Contract (GIC)**
Insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

**Index Credit Hedge Margin**
A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

**Index Credit**
Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to policy values that is linked to an index or indices. Amounts credited to the policy resulting from a floor on an index account are included.

**Index Crediting Strategy**
The strategy defined in a contract to determine index credits for a contract. This refers to underlying index, index parameters, date, timing, and other elements of the crediting method.

**Index Parameter**
Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

**Longevity Reinsurance**
An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with

*Commented [A14]:* Is “typically” intended to be a requirement in the definition? That is, to qualify as FIA does there need to be guaranteed principle?

*Commented [A15]:* We would suggest adding performance trigger to the list, along with other potential crediting methods; alternatively, the definition could specify that the crediting methods listed are examples only.

*Commented [A16]:* The definition states that “Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition”. Why is this the case and does this imply that longevity swaps are not within the scope of VM-22? Recommend adding the to the out of scope list in “2.A. Scope” if that is the case. Clarification would also be helpful on what guidance should be used for these agreements if out of scope for VM-22. Further, we would suggest removing “typically” from the definition.
periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

**Market Value Adjustment (MVA) Annuity**

An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

**Modified Guaranteed Annuity (MGA)**

A type of market-value adjusted annuity contract where the underlying assets are held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values that are based upon a market-value adjustment formula if held for shorter periods.

**Multiple Year Guaranteed Annuity (MYGA)**

A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

**Pension Risk Transfer (PRT) Annuity**

An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

**Registered Index-Linked Annuity (RILA)**

An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

---

Commented [A17]: We recommend editing the definition as follows: "A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account where the underlying assets are most commonly held in an insurance company separate account..."?

Commented [A18]: Is "typically" intended to be a requirement in the definition? That is, to qualify as PRT must the insurance company have the asset risk?

Consistent with the comment on Longevity Reinsurance, it would be helpful to clarify where a longevity swap contract falls within these definitions. Notably, index-based longevity swaps should be out of scope as they do not meet definition of "annuity contract" in SSAP 50. It should also be made explicit that PRT contracts can include lump sum benefits, death benefits and cash balance benefits as well.

Commented [A19]: It is unclear to us why RILA is defined in VM-22 when it is being used to exclude the product from VM-22 requirements.
Single Premium Immediate Annuity (SPIA)
An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within one year after (or from) the issue date.

Single Premium Deferred Annuity (SPDA)
An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.

Stable Value Contract
A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

Structured Settlement Contract (SSC)
A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

Synthetic GIC
Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the policyholder or plan trust.

Term Certain Payout Annuity
A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

Two-Tiered Annuity
A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.
Section 2: Scope and Effective Date

A. Scope

Subject to the requirements of this VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

- Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
- GICs
- Synthetic GICs
- Stable Value Contracts
- Funding Agreements

Products in scope of VM-22 include fixed annuities which consist of, but are not limited to, the following list:

- **Account Value Based Annuities**
  - Deferred Annuities (SPDA & FPDA)
  - Multi-Year Guarantee Annuities (MYGA)
  - Fixed Indexed Annuities (FIA)
  - Market-Value Adjustments (MVA)
  - Two-tiered Annuities
  - Guarantees/Benefits/Riders on Fixed Annuity Contracts
- **Payout Annuities**
  - Single Premium Immediate Annuities (SPIA)
  - Deferred Income Annuities (DIA)
  - Term Certain Payout Annuity
  - Pension Risk Transfer Annuities (PRT)
  - Structured Settlement Contracts (SSC)
  - Longevity Reinsurance

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.

B. Effective Date & Transition

**Effective Date**

These requirements apply for valuation dates on or after January 1, 2024.

**Transition**

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the
first three years following the effective date of VM-22 PBR. If a company during the three years elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve (following the requirements of Section 4) less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

Guidance Note: Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves, per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined

D. The Stochastic Reserve

1. The stochastic reserve shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.F herein.

2. The stochastic reserve amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles:
   a. Aggregate in a manner that is consistent with the company’s risk management strategy and reflects the likelihood of any change in risk offsets that could arise from shifts between product types, and
   b. Using prudent actuarial judgement, consider the following elements when aggregating groups of contracts: whether groups of contracts are part of the same portfolio (or different portfolios that interact), same integrated risk management system, administered/managed together

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

Commented [A25]: Guidance is needed on how a pre-reinsurance reserve is to be determined.

Commented [A26]: The term "Deterministic Certification Option" may be confusing, as there is no "deterministic" reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the phrasing to "with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E."
5. To the extent that these limits on aggregation result in more than one model segment, the
stochastic reserve shall equal the sum of the stochastic reserve amounts computed for each model
segment and scenario reserve amounts computed for each model segment for which the company
elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test

1. To the extent that certain groups of contracts pass one of the defined stochastic exclusion tests in
Section 7.B, these groups of contracts may be valued using the methodology pursuant to
applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for
immediate annuities specified in Section 13.

   a. For dividend-paying contracts, a dividend liability shall be established upon following
requirement in VM-A and VM-C, as described above, for the base contract.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option
to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in
accordance with Aetiological Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs
issued before 2018; AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on/after 2018;
Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33
methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contracts when performing the exclusion tests should follow the same
principles that underlie the aggregation approach for model segments discussed for Stochastic
Reserves in Section D above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements
using the method outlined in Section 12.

G. Prudent Estimate Assumptions:

1. With respect to the Stochastic Reserve in Section 3.C, the company shall establish the
prudent estimate assumption for each risk factor in compliance with the requirements in
Section 12 of Model #820 and must periodically review and update the assumptions as
appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall
annually review relevant emerging experience for the purpose of assessing the
appropriateness of the anticipated experience assumption. If the results of statistical
testing or other testing indicate that previously anticipated experience for a given factor is
inadequate, then the qualified actuary shall set a new, adequate, anticipated experience
assumption for the factor.

3. To determine the prudent estimate assumptions, the stochastic reserve shall also follow
the requirements in Sections 4 and 9 for asset assumptions, Section 10 for policyholder
behavior assumptions, and Section 11 for mortality assumptions.
Section 4: Determination of Stochastic Reserve

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Section 4.D. The company shall project cash flows including the following:

a. Revenues received by the company including gross premiums received from the policyholder (including any due premiums as of the projected start date).

b. All material benefits projected to be paid to policyholders—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.

Guidance Note: Amounts charged to account values on general account business are not revenue; examples include rider charges and expense charges.

c. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.J.

d. Insurance company expenses (including overhead and investment expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).

e. Net cash flows associated with any reinsurance.

f. Cash flows from hedging instruments as described in Section 4.A.4.

g. Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

h. If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.

Guidance Note: Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy...
loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance).

2. Grouping of Index Crediting Strategies

Index crediting strategies may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

3. Model Cells

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.

4. Modeling of Hedges

a. For a company that does not have a future hedging program tied directly to the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

   a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

   b) No hedge positions—in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Commented [A34]: Suggest editing the first sentence to note scope is FIAs and to avoid confusion regarding the term “investment guideline” as follows: “Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy.”

Commented [A35]: Given that Section 9 covers hedging, we would suggest considering moving parts of Section 4.A.4 to that section.

Commented [A36]: Suggest rewording “Future hedging program” to “hedging program with future transactions” to avoid ambiguity.
A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program tied directly to the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders.

b) Existing hedging instruments that are currently held by the company for this purpose in support of the contracts falling under the scope of these requirements shall be included in the starting assets. Existing hedging instruments that are currently held by the company for any other purpose should be modeled consistently with the requirements of Section 4.A.4.a.ii.

c) An Index Credit Hedge Margin for these instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible company experience and be no less than [X%] multiplicatively of the interest credited. In the absence of sufficient and credible company experience, a margin of [Y%] shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than [Y%]. It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve.

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future.

Commented [A37]: “Any other purpose” in the last sentence seems overly broad and should be narrowed.

Commented [A38]: We believe the company should determine the appropriate margin based on their demonstration of effectiveness. Any guardrails on these undetermined values should be minimal, including as low as 0, subject to the appropriate demonstration of effectiveness. Further, we believe that documentation of effective product management should be contemplated in addition to historical effectiveness.
Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve as the weighted average of two CTE values; first, a CTE70 (“best efforts”) representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE70 (“adjusted”) which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i, the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.i.c).

d) The use of products not falling under the scope of these requirements as a hedge shall not be recognized in the determination of accumulated deficiencies.

Guidance Note: Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other fixed income assets supporting the contracts, and a margin is reflected rather than modeling using a CTE70 adjusted run with no future hedge purchases. If a company has a more comprehensive hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or economic hedging), an appropriate and documented bifurcation method should be used in the application of sections 4.A.4.b.i and 4.A.4.b.ii above for the hedge modeling and justification. Such bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

Guidance Note: The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.

5. Revenue Sharing

If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each of the requirements set forth in VM 21 Section 4.A.5 are met.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods.

Commented [A39]: Margins are discussed in a different section, so recommend deleting.

Commented [A40]: Unclear why Revenue Sharing is considered for non-variable products, can probably delete.
7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. For a given scenario, the scenario reserve shall be determined using one of two methods described below:
   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   Guidance Note: The greatest present value of accumulated deficiencies can be negative.

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defeasement of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period.

   The scenario reserve for any given scenario shall not be less than the cash surrender value in aggregate on the valuation date for the group of contracts modeled in the projection.

2. Discount Rates

   In determining the scenario reserve, unless using the direct iteration method pursuant to Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

   a. The additional invested asset portfolio for a scenario is a portfolio of general account assets as of the valuation date, outside of the starting asset portfolio, that is required in that projection scenario so that the projection would not have a positive accumulated deficiency at the end of any projection year. This portfolio may include only (i) General Account assets available to the company on the valuation date that do not constitute part of the starting asset portfolio; and (ii) cash assets.

   Guidance Note:

   Additional invested assets should be selected in a manner such that if the starting asset portfolio were revised to include the additional invested assets, the projection would not be expected to experience any positive accumulated deficiencies at the end of any projection year.

   It is assumed that the accumulated deficiencies for this scenario projection are known.

   b. To determine the NAER on additional invested assets for a given scenario:
i. Project the additional invested asset portfolio as of the valuation date to the end of the projection period,
   a) Investing any cash in the portfolio and reinvesting all investment proceeds using the company’s investment policy.
   b) Excluding any liability cash flows.
   c) Incorporating the appropriate returns, defaults and investment expenses for the given scenario.

ii. If the value of the projected additional invested asset portfolio does not equal or exceed the accumulated deficiencies at the end of each projection year for the scenario, increase the size of the initial additional invested asset portfolio as of the valuation date, and repeat the preceding step.

iii. Determine a vector of annual earned rates that replicates the growth in the additional invested asset portfolio from the valuation date to the end of the projection period for the scenario. This vector will be the NAER for the given scenario.

iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.e, as a safe harbor.

**Guidance Note:** There are multiple ways to select the additional invested asset portfolio at the valuation date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

   The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

   Treasury Department interest rate curves, as well as investment return paths for index funds, equities, and fixed income assets shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.
D. Projection of Assets

1. Starting Asset Amount
   a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:
      i. Any hedge instruments held in support of the contracts being valued; and
      ii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i).
   b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets
   For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

Guidance Note: Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets
   a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:
      i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;
The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

For purchases of other fixed income investments, if included in the model investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

Notwithstanding the above requirements, the model investment strategy and any non-prescribed asset spreads shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained by substituting an alternative investment strategy in which all fixed income reinvestment assets are public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

- 5% Treasury
- 15% PBR credit rating 3 (Aa2/AA)
- 40% PBR credit rating 6 (A2/A)
- 40% PBR credit rating 9 (Baa/BBB)

Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.ii and Section 4.D.4.a.iv, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.
Guidance Note: This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F.

b. Cash flows from general account index funds and equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

Commented [A43]: Request clarification around the meaning of “general account index funds”.

NAIC Proceedings – Summer 2022
Attachment Twenty-Five-C
Life Actuarial (A) Task Force
8/8–9/22
c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.I.

E. Projection of Annuitzation Benefits

1. Assumed Annuitzation Purchase Rates

   a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such payout rates shall reflect the payout rate specified in the contract.

   b. For purposes of projecting future elective annuitization benefits and withdrawal amounts from GMWBs, the projected annuitization purchase rates shall be determined assuming that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuitzation Options

   For contracts projected to elect future annuitization options (including annuitizations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections may assume the contract will stay in force, the projected periodic payments are paid, and the associated maintenance expenses are incurred.

F. Frequency of Projection and Time Horizon

1. Use of an annual cash-flow frequency (“timestep”) is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

2. Care must be taken in simulating fee income and expenses when using an annual time step. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

   Guidance Note: As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs

When determining a stochastic reserve, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.
Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both a post-reinsurance ceded and a pre-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

i. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

ii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iii. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the aggregate reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum reserve by the absolute value of such reductions in surplus.

b. In order to determine the stochastic reserve on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard coinsurance treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection.
based on using starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable method.

Guidance Note: For standard pro rata insurance treaties (does not include experience refunds), where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld coinsurance; modified coinsurance; coinsurance with a trust. To the extent these assets would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard coinsurance treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, Principle-Based Reserves for Life Products under the NAIC Valuation Manual, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsured policies belong and reflect the terms of the reinsurance agreement.

3. Reserve Determined Upon Passing the Exclusion Test

If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance and post-reinsurance reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance reserves might not.

4. To Be Determined
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation if the stochastic exclusion test (SET) is satisfied for that group of contracts. The company has the option to calculate or not calculate the SET.
   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.
   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups of contracts. If the reserve methodology described in Section 4 is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.
   c. A company may not exclude a group of contracts from the stochastic reserve requirements if there are one or more future hedging programs associated with the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9.A.1.

B. Types of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

1. Stochastic Exclusion Ratio Test (SERT)—Annually the company demonstrates that the groups of contracts pass the SERT defined in Section 7.C.

2. Stochastic Exclusion Demonstration Test—In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.

3. SET Certification Method—For groups of contracts that do not have guaranteed living benefits, future hedging programs, or pension risk transfer business in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts is not subject to material aggregate risk levels across interest rate risk, longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

Guidance Note: The qualified actuary should develop documentation to support the actuarial certification that presents his or her analysis clearly and in detail sufficient for another actuary to understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not subject to material interest rate risk, longevity risk, or asset return volatility risk. Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:

Commented [A47]: We recommend removing “pension risk transfer business” from products scoped out of SET certification method. It is unclear why this business would be treated differently from individually issued business for testing intended to capture interest rate risk.
a) A demonstration that using requirements under VM-A and VM-C for the group of contracts calculated are at least as great as the assets required to support the group of contracts using the company’s cash-flow testing model under each of the 16 scenarios identified in this section or alternatively each of the New York seven scenarios.

b) A demonstration that the group of contracts passed the SERT within 36 months prior to the valuation date and the company has not had a material change in its interest rate risk.

c) A qualitative risk assessment of the group of contracts that concludes that the group of contracts does not have material interest rate risk or asset return volatility. Such assessment would include an analysis of product guarantees, the company’s non-guaranteed elements (NGEs) policy, assets backing the group of contracts and the company’s investment strategy.

C. Stochastic Exclusion Ratio Test

1. In order to exclude a group of contracts from the stochastic reserve requirements under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of \((b-a)/a\) is less than \([x]\)% where:

   a. \(a\) = the adjusted scenario reserve described in Paragraph C.2.a.i below using economic scenario 9, the baseline economic scenario, as described in Appendix 1.E of VM-20.

   b. \(b\) = the largest adjusted scenario reserve described in Paragraph C.2.b below under any of the other 15 economic scenarios described in Appendix 1.E of VM-20 under both \([95]\)% and \([105]\)% of anticipated experience mortality excluding margins.

Guidance Note: Note that the numerator should be the largest adjusted scenario reserve for scenarios other than the baseline economic scenario, minus the adjusted scenario reserve for the baseline economic scenario. This is not necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario, or the absolute value of the biggest difference from the adjusted scenario reserve for the baseline economic scenario, both of which could lead to an incorrect test result.

2. In calculating the ratio in subsection (1) above:

   a. The company shall calculate an adjusted scenario reserve for the group of contracts for the 16 scenarios that is equal to either (i) or (ii) below:

      i. The scenario reserve defined in Section 4, but with the following differences:

         a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph C.1.b of this section.

         b) Using the interest rates and equity return assumptions specific to each scenario.

         c) Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.
d) Shall reflect future mortality improvement in line with anticipated experience assumptions.

e) Shall not reflect correlation between longevity and economic risks.

ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:

a) Using the interest rates and equity return assumptions specific to each scenario.

b) Using the mortality scalars described in Paragraph C.1.b of this section.

c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current 16 economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.

e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the exclusion test under a pre-reinsurance-ceded basis upon determining the pre-reinsurance reserve-ceded aggregate reserve.

3. If the ratio calculated in this section is less than [x]% pre-non-proportional reinsurance, but is greater than [x]% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation • SERT = the ratio (b–a)/a defined in Section 7.C.1 above

a) The pre-non-proportional reinsurance results are “gross of non-proportional,” with a subscript “gn,” so denoted SERT

b) The post-non-proportional results are “net of non-proportional,” with subscript “nn,” so denoted SERT
ii. If a block of business being tested is subject to one or more non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurance but ignoring the non-proportional contract(s), and “net of non-proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.

iii. So, if \( SERT_{gn} \leq \{x\} \) but \( SERT_{nn} > \{x\} \), then compute the largest percent increase in reserve (LPIR) = \( \frac{b-a}{a} \), both “gross of non-proportional” and “net of non-proportional.”

\[
LPIR_{gn} = \frac{b_{gy} - a_{gy}}{a_{gy}}
\]

\[
LPIR_{nn} = \frac{b_{ny} - a_{ny}}{a_{ny}}
\]

Note that the scenario underlying \( b_{gn} \) could be different from the scenario underlying \( b_{nn} \).

If \( SERT_{nn} \times LPIR_{nn}/LPIR_{gn} < \{x\} \), then the block of contracts passes the SERT.

b. Another more qualitative approach is to calculate the adjusted scenario reserves for the 16 scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.

4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve requirements using the methodology in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

a. The demonstration shall provide a reasonable assurance that if the stochastic reserve was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve requirements.

b. If, as of the end of any calendar year, the company determines the aggregate reserve for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.

Commented [A51]: We believe subscript "gy" should be "gn".

Commented [A52]: Does this statement imply a floor reserve of VM-A and VM-C? VM-20 does require the NPR as the floor of the reserve but as written, VM-22 does not require a floor reserve. Recommend removing 1.a. Same statement with the 2.a statement demonstration. This requirement does not apply to the other permitted tests, which seemed counterintuitive.
c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an explanation of why the use of such a date will not produce a material change in the outcome, as compared to results based on an analysis as of the valuation date.

d. The demonstration shall provide an effective evaluation of the residual risk exposure remaining after risk mitigation techniques, such as derivative programs and reinsurance.

2. The company may use one of the following or another method acceptable to the insurance commissioner to demonstrate compliance with subsection 7.D.1 above:

a. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve calculated on a stand-alone basis.

b. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the scenario reserve that results from each of a sufficient number of adverse deterministic scenarios.

c. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve calculated on a stand-alone basis, but using a representative sample of contracts in the stochastic reserve calculations.

d. Demonstrate that any risk characteristics that would otherwise cause the stochastic reserve calculated on a stand-alone basis to exceed the statutory reserve calculated in accordance with VM-A and VM-C, are not present or have been substantially eliminated through actions such as hedging, investment strategy, reinsurance or passing the risk on to the policyholder by contract provision.

E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve for a group of contracts using a single deterministic economic scenario, subject to the following conditions.

a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recurring premium payments, and guaranteed living benefits.

b. The company certifies that the group of policies is not supported by a reinvestment strategy that contains future hedge purchases.

c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing the scenario reserve volatility across various economic scenarios.
d. The company must disclose a description of contracts and associated features in the certification.

Drafting Note: Consider revisiting Paragraph E.1.c to possibly either require i) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario; or ii) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve for the group of contracts under the Deterministic Certification Option is determined as follows:

a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).

b. The stochastic reserve equals the scenario reserve following the requirements for Section 4.

Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company (a) only hedges index credits, or (b) clearly separates index credit hedging from other hedging. In those situations, the modeling of hedges supporting index credits can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.4.b.i.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the calculation of the stochastic reserve, determined in accordance with Section 3.D and Section 4.D.

3. The company shall take into account the costs and benefits of hedge positions expected to be held by the company in the future along each scenario. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than [6] months.

4. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. This also is referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which also is referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

5. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserve otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserve needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserve attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock tested.

Guidance Note: No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

C. Calculation of Stochastic Reserve (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no hedging strategy except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.i.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserve is given by:

\[
\text{Stochastic reserve} = \text{CTE70 (best efforts)} + \frac{E}{2} \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}]
\]
4. The company shall specify a value for \( E \) (the "error factor") in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of \( E \). The value of \( E \) may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, \( E \) must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recent 12 months, to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for \( E \).

6. Such a back-test shall involve one of the following analyses:

   a. For companies that model hedge cash flows directly ("explicit method"), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses – both realized and unrealized – observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g. reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

      To support the choice of a low value of \( E \), the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of \( E \) by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

   b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an "implicit method" or "cost of reinsurance method"), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

      i. Determine the hedge asset gains and losses—both realized and unrealized—inurred over the month attributable to equity, interest rate, and implied volatility movements.

      ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).

      iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.
iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with no history, E should be at least 0.50. However, E may be lower than 0.50 if some reliable experience is available and/or if the change in strategy is a refinement rather than a substantial change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for...
purposes of reducing the stochastic reserve, the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or adverse estimates of the parameters.

A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the fixed indexed annuities and other in-scope products and the same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited to, a hedging strategy where material hedging assets will be obtained when the fixed indexed annuity account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the fixed indexed annuities and other in-scope products and the same sensitivities associated with the hedging assets. There may be scenarios that are particularly costly to discontinuous hedging strategies, especially where those result in large discontinuous changes in sensitivities (Greeks) associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve otherwise calculated.

Commented [A56]: Suggest replacing “indexed” with “fixed” since this would apply to all fixed annuities.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the results. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to...
completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more behaviors.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.

2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
b. Surrenders.
c. Partial withdrawals (systematic and elective).
d. Account transfers (switching/exchanges).
e. Resets/ratchets of the guaranteed amounts (automatic and elective).
f. Future deposits.
g. Income start date
h. Commutation of benefit (from periodic payment to lump sum)

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions.

For example:

a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing, ) or if the contract provisions incentivize the contract holders to transfer between accounts.

b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).

c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.

4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):

a. Gender.
b. Attained age.
c. Issue age.
d. Contract duration.
e. Time to maturity.
f. Tax status.
g. Account value.
h. Interest credited (current and guaranteed).
i. Available indices.
j. Guaranteed benefit amounts.
k. Surrender charges, transfer fees or other contract charges.
l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.
6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., the non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holder.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practicality, the use of dynamic models is encouraged, but not mandatory. Risk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers) may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of behavior consistent with the economic scenarios and other variables in the model, including the non-scenario tested assumptions. The company shall test the sensitivity of results to understand the materiality of making alternate assumptions and follow the guidance discussed above on setting assumptions for sensitive behaviors.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution). To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the model) in order to determine exactly which scenario results are included in the CTE measure. Rather, in light of the products being valued, the company should be mindful of...
the general characteristics of those scenarios likely to represent the tail of the loss distribution and consequently use prudent estimate assumptions for behavior that are reasonable and appropriate in such scenarios. For fixed annuities, these “valuation” scenarios would typically display one or more of the following attributes:

a. Declining and/or volatile index values, where applicable.
b. Price gaps and/or liquidity constraints.
c. Rapidly changing interest rates or persistently low interest rates.
d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions:

a. Remain logically and internally consistent across the scenarios tested.
b. Represent plausible outcomes.
c. Lead to appropriate, but not excessive, asset requirements.

4. The company should remember that the continuum of “plausibility” should not be confined or constrained to the outcomes and events exhibited by historic experience.

5. Companies should attempt to track experience for all assumptions that materially affect their risk profiles by collecting and maintaining the data required to conduct credible and meaningful studies of contract holder behavior.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:

a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.
b. Complies with the contract holder behavior requirements stated in Section 10 above in this section.

Commented [A61]: Suggesting deleting as we are not aware of dynamic credit spreads typically being modeled.
2. If the company models policy loans explicitly, the company shall:
   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.
   b. Assign loan balances either to exactly match each policy’s utilization or to reflect average utilization over a model segment or sub-segments.
   c. Model policy loan interest in a manner consistent with policy provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
   d. Model policy loan principal repayments, including those that occur automatically upon death or surrender. Include policy loan principal repayments as a positive policy loan cash flow, per Section 4.A.1.h.
   e. Model additional policy loan principal. Include additional policy loan principal as a negative policy loan cash flow, per Section 4.A.1.h (but do not include interest added to the loan balance as a negative policy loan cash flow).
   f. Model any investment expenses allocated to policy loans and include them either with policy loan cash flows or insurance expense cash flows.

1. Non-Guaranteed Elements

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy costs or values and not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to fixed annuities include but are not limited to the following: fixed credited rates, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollup rates, rollup period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.J.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.
4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of an NGE that:
   a. Is not based on some aspect of the policy’s or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

   However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.
   a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve.
   b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the stochastic reserve. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.)

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contractor-specific mortality experience data or relevant pooled data from annuitants drawn from different industries or geographies that may be used to sub-divide inforce blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to...
how payout annuities vs. deferred annuities are distinguished.

**Guidance Note:** Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.

4. **Margin for Data Uncertainty**

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a plus (minus) segment to a minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

**B. Determination of Expected Mortality Curves**

1. **Experience Data**

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2. for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. **Data Other Than Direct Experience**

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. **No Data Requirements**

i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:
a. [2021 SOA Deferred Annuity Mortality Table] with [Projection Scale G2] for individual deferred annuities that do not contain guaranteed living benefits

\[ q_{x}^{2021+n} = q_{x}^{2021}(1 - G_{x})^{n} \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage (Fx) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual payout annuity contracts and deferred annuity contracts with guaranteed living benefits

\[ q_{x}^{2012+n} = q_{x}^{2012}(1 - G_{x})^{n} + F_{x} \]

b. [1983 Table “a”] for structured settlements or other contracts with impaired mortality
c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_{x}^{1994+n} = q_{x}^{1994}(1 - AA_{x})^{n} \]

Commented [A64]: For PRT an assumption based on a third-party data provider would be better than the industry table to get contract-specific mortality assumptions. Is this permitted? The guidance note in A.3 seems to get at this, but it’s not clear in B.3.ii.c whether this is allowed. This is an important distinction as PRT population can vary from those populations the tables are based upon.
iii. For a business segment with non-U.S. insureds, an established industry or national mortality table may be used, with approval from the domiciliary commissioner.

4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

a. Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

b. Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by contract duration for an appropriate select period. As an alternative, if the company determines that mortality is affected by selection, the company could apply margins to the expected mortality in such a way that the actual mortality modeled does not depend on contract duration.

c. Modification and Relevance of Data

Commented [A65]: The phrase "When little or no experience or information is available on a business segment" is not included, unlike in (i) and (ii) of the same sub-section. It appears to be the intent that this is the only situation in which this would apply, but it would be helpful to make this explicit.
Even for a large company, the quantity of life exposures and deaths are such that a significant amount of smoothing may be required to determine expected mortality curves from mortality experience. Expected mortality curves, when applied to the recent historic exposures (e.g., three to seven years), should not result in an estimate of aggregate number of deaths less (greater) than the actual number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying data), older data may no longer be relevant. The “age” of the experience data used to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors that include, but are not limited to, trends in mortality experience, trends in exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative to mortality by amounts, changes in the mix of business and product features that could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves with the mortality assumption described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

Guidance Note: For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the mortality table used in the blending.

2. Adjustment of Statutory Valuation Mortality for Improvement

For purposes of the adjustment for credibility, the mortality table for a plus segment may be and the mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.

b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.
f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve. If such an adjustment would reduce the stochastic reserve, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

Table 12.1: Sample Allocation of Aggregate Reserve

<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>

Commented [A68]: We believe discussion of allocation of aggregate reserves should be analyzed as part of the field study.
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

**Option 2: Actuarial Present Value Approach**

B. The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve defined in Section 3.D.
   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.
   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve defined in 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

<table>
<thead>
<tr>
<th>Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value Li = (Ai)/2[Ai][Aggregate Reserve - 2Ci]</th>
<th>9.09</th>
<th>10.91</th>

*Cash Surrender Value
**Guaranteed Lifetime Withdrawal Benefit

**Guidance Note:** The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 13: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section:

   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

Guidance Note: For Section 13.A.2.d, Section 13.A.2.e, Section 13.A.2.f and Section 13.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:

   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 13.A.2.d, Section 13.A.2.e, Section 13.A.2.f, Section 13.A.2.g or Section 13.A.2.h, the company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such...
permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 13 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B) (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C) (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 13.B.1.c above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   **Guidance Note:** If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.

3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.
The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her age last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 13 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*
   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.
   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

   Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

Table 3-2: Assignment to Valuation Rate Bucket by Reference Period and Initial Age

<table>
<thead>

</tr>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
Guidance Note: For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

b. Immaterial Change in Consideration

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

3. Statutory Maximum Valuation Interest Rate

a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 13.C.1) and its Premium Determination Date (Section 13.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

d. Quarterly Valuation Rate:

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ Q = R + S - D - E \]

Where:

a. \( R \) is the reference rate for that Valuation Rate Bucket (defined in Section 13.C.4);

b. \( S \) is the spread rate for that Valuation Rate Bucket (defined in Section 13.C.5);

c. \( D \) is the default cost rate for that Valuation Rate Bucket (defined in Section 13.C.6);
and

d. E is the spread deduction defined as 0.25%.

e. Daily Valuation Rate:

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[ I_d = I_q + C_{d-1} - C_q \]

Where:

a. \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b. \( C_{d-1} \) is the daily corporate rate (defined in Section 13.C.7) for the business day immediately preceding the premium determination date; and

c. \( C_q \) is the average daily corporate rate (defined in Section 13.C.8) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate \( (I_d) \) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4. Reference Rate

Reference rates are updated quarterly as described below:

a. The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b. Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c. The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 13.C.9) effective for the calendar year in which the premium determination date falls.

5. Spread

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a. Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.I) effective for the calendar year in which the premium determination date falls.

6. Default costs for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 13.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAML0A0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAML2A0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAML3A0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAML4A0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAML7A0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAML8A0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 13.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 13.C.7.a].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 13.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating $I_i$ in Section 13.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:
   i. Bucket A:
      a) Single Life Annuity age 91 with 0 and five-year certain periods.
      b) Five-year certain only.
   ii. Bucket B:
      a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
      b) 10-year certain only.
   iii. Bucket C:
      a) Single Life Annuity age 70 with 0 and 15-year certain periods.
      b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
      c) 15-year certain only.
   iv. Bucket D:
      a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
      b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. 
   (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.
g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

**Weight Tables 2 through 4**

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:
   a) Column 1 of Table 4 is identical to column 1 of Table 1.
   b) Column 2 of Table 4 is 50% of column 2 of Table 1.
   c) Column 3 of Table 4 is identical to column 2 of Table 4.
   d) Column 4 of Table 4 is 50% of column 3 of Table 1.
   e) Column 5 of Table 4 is identical to column 4 of Table 4.
   f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. **Group Annuity Contracts**

   For a group annuity purchased under a retirement or deferred compensation plan (Section 13.A.2.i), the following apply:

   a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

   **Guidance Note:** Under some group annuity contracts, certificates may be purchased on different dates.

   b. In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

   **Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.
Valuation Manual Section II: Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for fixed annuity contracts issued prior to 1/1/2024 are those requirements as found in VM-A and VM-C as applicable, with the exception of the minimum requirements for the valuation interest rate for single premium immediate annuity contracts, and other similar contracts, issued after Dec. 31, 2017, including those fixed payout annuities emanating from host contracts issued on or after Jan. 1, 2017, and on or before Dec. 31, 2017. The maximum valuation interest rate requirements for those contracts and fixed payout annuities are defined in Section 13 of VM-22, Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves.

D. Minimum reserve requirements for fixed annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 12 of VM-22.

E. The below principles may serve as key considerations for assessing whether VM-21 or VM-22 requirements apply:

1. Index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for application of VM-22 requirements:
   a. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.
   b. Credits a rate of interest under the contract that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

   Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

2. Index-linked or modified guaranteed annuity contracts that do not satisfy either of the two conditions listed above in Paragraph E.1.i and E.1.ii may be a key consideration for application of VM-21 requirements.
Subsection 6: Riders and Supplemental Benefits

**Guidance Note:** Policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraph C above including, but not limited to, Guaranteed Minimum Accumulation Benefits, Guaranteed Minimum Death Benefits, Guaranteed Minimum Income Benefits, Guaranteed Minimum Withdrawal Benefits, Guaranteed Lifetime Income Benefits, Guaranteed Lifetime Withdrawal Benefits, Guaranteed Payout Annuity Floors, Waiver of Surrender Charges, Return of Premium, Systematic Withdrawal Benefits under Required Minimum Distributions, and all similar guaranteed benefits shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

   1. The rider or supplemental benefit does not have a separately identified premium or charge.

   2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.

   3. After issuance, the base policy or contract value or benefits are determined by referencing the rider or supplemental benefit features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

F. If a term life insurance rider on the named insured[s] on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.
G. For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

H. Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.

Commented [A70]: This section states that “When advantageous, policyholders will commence living benefit payouts if not started yet.” This text seems to directly contradict VM-22 Section 6.H.2 which states “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally.” We suggest revising 6.H.2 to align with the text of 10.D.8.
Equitable appreciates the opportunity to comment on the exposed Fixed Annuity PBR framework. Below are our views on two key aspects of the framework: (1) Standard Projection Amount; and (2) Aggregation of Reserves. The remainder of our views are appropriately captured in the ACLI comment letter.

**Standard Projection Amount (SPA):** Equitable favors the Standard Projection Amount as a binding floor over a non-binding disclosure item. A binding Standard Projection Amount mitigates the risk of overly optimistic company assumptions feeding reserves that will ultimately be insufficient to pay for future policyholder obligations. We cite several reasons in support of its use as a binding floor:

- **Success of precedent:** VM-21 is the industry precedent for holding a Standard Projection Amount as a binding floor. While some argue that this aspect of the framework may produce a non-economic reserve, in practice, the VM-21 Standard Projection Amount has had no such effect; rather, we believe its enactment motivated several companies to strengthen their weakest assumptions.

- **Resource prioritization:** The scope of VM-22 is vast, and therefore the Standard Projection Amount assumptions may be resource-intensive to develop. We believe that making the Standard Projection a binding floor will attract appropriate focus on its calibration.

- **Leverages valuable industry data:** Companies have differential amounts of experience data upon which to formulate assumptions. The SPA will ensure companies without access to credible experience data have a guardrail to use in their otherwise judgmental assumption setting process.

- **Safeguard against actuarial judgment for untested assumptions:** The Standard Projection Amount allows regulators to safeguard the industry against historically untested assumptions, such as policyholder behavior (e.g. lapses) when interest rates change significantly from business conditions at issue, or very long-dated lapse or persistency risk.

- **Addresses a priority gap in the regulatory framework:** The mis-estimation of complex actuarial processes has been the root cause behind the most acute insurer insolvencies. At present, the reserve and capital framework (a) omit any RBC charge for the preponderance of complex actuarial risks and (b) the provision for adverse deviations in reserves has frequently failed to protect insurers from severe losses. The establishment of properly calibrated guardrails on assumptions material in impact and high in uncertainty will eliminate the likelihood of severe insolvencies driven by actuarial mis-estimation and rectify a gap in the regulatory framework.

We also recommend that regulators carefully define the scope of the Standard Projection Amount assumptions and, for insignificant assumptions that are difficult to develop, rely on the company’s own principles-based assumptions with appropriate scrutiny and disclosure.
Aggregation of Reserves / Reserving Categories: Per Equitable’s December 2020 comment letter, we support full aggregation for purposes of calculating the VM-22 reserve as the aggregation of risk is at the core of the insurance industry. As noted previously, the key risk of including aggregation within reserving is the risk that the projected profits are not realized and are not available to supplement reserves for in-the-money contracts/product lines. As such, the risk of aggregation equates to the risk that economic and policyholder behavior assumptions on profitable product lines are not realized. These risks can be mitigated through mechanisms such as a binding Standard Projection Amount that ensures company assumptions are not idealistic.

If less than full aggregation was permitted, we support splitting products based on payout vs. accumulation phase as reflected in Option 2 in the exposure draft.

Conclusion: Equitable appreciates the opportunity to comment on the exposed VM-22 proposal and we look forward to continuing to work with regulators to reach an appropriate principle based reserving framework for fixed annuities. We are available to discuss our comments further as desired.

Sincerely,

Stephen Tizzoni, Head of Actuarial Regulatory Affairs
Valuation Manual (VM)-22 (A) Subgroup
Virtual Meeting
April 13, 2022

The VM-22 (A) Subgroup of the Life Actuarial (A) Task Force met April 13, 2022. The following Subgroup members participated: Ben Slutsker, Chair (MN); Ahmad Kamil, Elaine Lam, and Thomas Reedy (CA); Lei Rao-Knight (CT); Mike Yanacheak (IA); Vincent Tsang (IL); Nicole Boyd (KS); William Leung (MO); Seong-min Eom (NJ); Bill Carmello and Amanda Fenwick (NY); Rachel Hemphill (TX); Tomasz Serbinowski (UT); and Craig Chupp (VA).

1. **Heard an Update on Revisions to VM-22**

Mr. Slutsker discussed a spreadsheet (Attachment Twenty-Six-A) developed to categorize the 378 comments on the American Academy of Actuaries’ (Academy’s) proposed revisions (Attachment Twenty-Six-B) to VM-22, Statutory Maximum Valuation Interest Rates for Income Annuities. He said the comments are categorized into four tiers based on significance: 1) Key Decision Points; 2) High Substance Edits; 3) Moderate Substance Edits; and 4) Noncontroversial or Low Substance Edits, with the preponderance of comments falling into the latter tier.

Mr. Slutsker said the implementation date of the VM-22 revisions is scheduled for January 2024 but hinges upon the completion of a VM-22 field test. He noted that the date of the VM-22 field test is dependent on the completion of the economic scenario generator (ESG) field test to be conducted by the Life Actuarial (A) Task Force. He said deferring the VM-22 field test to 2023 could push the VM-22 implementation date to January 2025.

Ms. Lam said the California Department of Insurance (CDI) Office of Principle-Based Reserving (OPBR) comments (Attachment Twenty-Six-C) on the revisions to VM-22 highlighted formatting and definitions that are inconsistent with what is used in VM-20, Requirements for Principle-Based Reserves for Life Products. She also suggested listing the products that are in scope ahead of the products that are not in scope.

Paul S. Graham (American Council of Life Insurers—ACLI) said the ACLI comment letter (Attachment Twenty-Six-D) advocates for a principle-based approach to determining whether an annuity product is covered by VM-22 or VM-21, Requirements for Principle-Based Reserves for Variable Annuities. Chris Conrad (Academy) said the Academy favors an exclusion approach, which would identify annuity products that are in scope for VM-21 and have all other annuities fall under VM-22. Mr. Graham said the ACLI would be comfortable with that approach. Mr. Leung suggested using the Indexed-Linked Variable Annuity (ILVA) as a test case when developing the principles. Mr. Graham agreed that the ACLI could develop draft language it could share with the Academy before presenting it to the Task Force. He suggested that once the principle-based language is deemed acceptable for VM-22, it should also be considered for use in VM-21.

Mr. Slutsker discussed the two options that the Subgroup considered in July 2021 for determining reserving categories for aggregating annuity contracts. He said the first option lists the specific products in the Payout Annuity Reserving category, and the second option uses the principle-based approach of broadly defining both the Payout Annuity Reserving category and the Accumulation Annuity Reserving category. Mr. Conrad said the Academy supports principle-based aggregation that is consistent with the company’s risk management strategy and reflects any potential risk offsets. He said the same aggregation principles should be applied to exclusion testing, CTE-70 calculation grouping, and comparing final reserve components. Ms. Hemphill said while the Texas Department of Insurance (TDI) supports full aggregation, it would support the decision of the Subgroup if it chose something more conservative. She caveated that the TDI would want the Subgroup’s position to be clearly defined. Mr. Carmello said the New York State Department of Financial Services (NYDFS) prefers Option 1 but
would like to see “Other” listed as the tenth product type of the list provided in Option 1. Steve Tizzoni (Equitable) said Equitable supports full aggregation as a core of the way risks are measured and managed. He said of the two available options, Equitable favors Option 2. Ms. Lam said the OPBR would be in favor of Option 2 if it also requires the company to disclose the thought behind each product categorization. Ms. Rao-Knight said she also prefers full aggregation but would support Option 2 with disclosures. Mr. Leung said he prefers Option 1, as it would provide clarity without requiring disclosures. Cindy Barnard (Pacific Life) said if a company has products with both disintermediation risk and longevity risk, the risks may fluctuate, making it difficult to disclose which is the greater risk at any given time. Mr. Slutsker called for a straw vote. Option 1 received seven votes, while Option 2 received four votes. Mr. Slutsker said Option 1 will serve as placeholder as VM-22 development continues.

Mr. Slutsker began discussion on the potential for including an exemption, like the VM-20 Life Principle-Based Reserving (PBR) exemption, in VM-22. Mr. Graham expressed the ACLI’s support of an exemption that may be applied to small blocks of business. He suggested that the exemption may be based on a comparison of reserves held in the previous year. Mr. Slutsker said exemption comments were also submitted by Erie Family Life (Attachment Twenty-Six-E). Ms. Hemphill, Mr. Leung, and Mr. Chupp agreed that an exemption of some type should exist. Mr. Tsang also agreed, but he added that the exemption should be accompanied by asset adequacy testing (AAT). Ms. Hemphill said requiring AAT concepts is more akin to an exclusion than an exemption criterion. Ms. Lam said the CDI OPBR suggested that the exemption should consider the nature of the block of business, in the same way the VM-20 exemption prohibits material universal life policies with secondary guarantees (ULSG) from exemption. Mr. Graham said he is concerned that the companies desiring exemption due to a lack of resources would also have challenges allocating the resources to AAT. The ACLI agreed to develop an initial draft of VM-22 exemption language in 45 days. John Robinson (unaffiliated) said historically, there has been concern that payout annuities are under reserved. He suggested that Subgroup members keep that issue in mind when deciding whether and how to allow exemptions.

Having no further business, the VM-22 (A) Subgroup adjourned.

https://NAICSupportStaffHub/Member Meetings/2022 NAIC Meetings/Spring National Meeting/Committee Meetings/LIFE INS and ANNUITIES (A) COMMITTEE/Life Actuarial (A) TF/Summer LATF Calls/VM-22 Subgroup/04 13/4_13 VM-22 Minutes.docx

Valuation Manual Section II. Reserve Requirements .......................................................................................... 8128
Subsection 2: Annuity Products ...................................................................................................................... 8128
Subsection 6: Riders and Supplemental Benefits .............................................................................................. 8329
Section 1: Background

A. Purpose

Sections 1 through 13 of these requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2024. Section 14 of these requirements establishes the maximum valuation rate for payout annuities for contracts issued on or after 1/1/2018. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts and certificates, the Commissioners Reserve Valuation Method (CRVM). Guidance Note: CRVM requirements apply to some group pension contracts.

B. Principles

The projection methodology used to calculate the stochastic reserve SR is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves. Guidance Note: The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

Principle 1: The objective of the approach used to determine the stochastic reserve SR is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

Principle 2: The calculation of the stochastic reserve SR is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cashflow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve SR at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles. Guidance Note: Examples where full aggregation between contracts may not be possible include experience rated group contracts and the operation of reinsurance treaties.

Principle 3: The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the

Commented [X3]: The proposal suggests VM-22 is not operative until 1/1/2024, which contradicts Section 13 and existing requirements. We would suggest wording this to clarify that Section 13 is effective after 12/31/2017. Further, we would suggest consistency in labeling of dates (either all text or all numeric).

Commented [CD4]: Might be clearer to refer to “Section 13” here.

Commented [X5]: The statement only addresses “contracts”. Recommend adding “and certificates”. Need to do a holistic review if where “and certificates” may be needed.

Commented [X6]: (Relationship to RBC Requirements): The VM-21 guidance note was not included in VM-22; however, we believe it would be appropriate to retain and reword to say, “products that calculate a stochastic reserve”, since the relationship to RBC would likely be maintained.

Commented [X7]: We would support consistent application of principles across all chapters as currently VM-20 does not have a like-set of principles. We believe this could involve a broader discussion of the assorted product requirements in the VM. As a shorter-term fix, we would recommend generalizing the principles where appropriate and moving these to “Section I. Introduction” or “VM-01” and equally applying to VM-20.

Commented [CD8]: For consistency, will this edit be considered for VM-21 as well?

Commented [X9]: We support this principle but note that later sections appear to contradict this principle. For example, the statement “The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario.” contradicts with the introduction of additional reserve categories and other limitations (such as model segment restrictions).

Commented [X10]: Principle 2: Recommend reinstating Guidance Note in Principle 2 to be consistent with VM-21.
company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the stochastic reserve SR at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve SR, the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

Guidance Note: The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle. More guidance and requirements for setting assumptions in general are provided in Section 12.

Principle 4: While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve SR is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

Principle 5: Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve SR. Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve SR without also reducing risk on scenarios similar to those used in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

C. Risks Reflected

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and
   b. Capable of materially affecting the reserve.
2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:

a. Asset risks
   i. Credit risks (e.g., default or rating downgrades).
   ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).
   iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).
   iv. Performance of equities, real estate, and Schedule BA assets.
   v. Call risk on callable assets.
   vi. Separate account fund performance.
   vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).
   viii. Currency risk.

b. Liability risks
   i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.
   ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.
   iii. Utilization risk associated with guaranteed living benefits.
   iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.
   v. Annuitzation risks.
   vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).
   vii. Applicable expense risks, including fluctuation in maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

b. Combination risks
   i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.
   ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).

Commented [CD17]: Can a non-variable annuity have a separate account fund? I am not aware of any such annuity. Furthermore, all references to separate accounts and fund performance were deleted from this draft. Thus, we should consider deleting this item from the list.

Commented [CD18]: Is there a distinction between “dump-ins” and “deposits”? Why are both words needed? Also, if it’s determined that both words are needed, should this same change be made in VM-21?

Commented [X19]: Recommend change to “fluctuation in” maintenance expenses for clarity.

Commented [CD20]: should this same change also be made to VM-21?

Commented [X21]: We recommend removing the bullet “Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above” as this is unclear and probably extraneous.
iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:
   a. Those not associated with the policies or contracts being valued, or their supporting assets.
   b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
      i. Liquidity risks associated with a sudden and significant levels of withdrawals and surrenders "run on the bank."
   b. Liability risks
      i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.
      ii. Catastrophic events (e.g., epidemics or terrorist events).
      iii. Major breakthroughs in life extension technology that have not yet fundamentally-altered recently observed mortality experience.
      iv. Significant future reserve increases as an unfavorable scenario is realized.
   c. General business risks
      i. Deterioration of reputation.
      ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.
      iii. Poor management performance.
      iv. The expense risks associated with fluctuating amounts of new business.
      v. Risks associated with future economic viability of the company.
      vi. Moral hazards.
      vii. Fraud and theft.
      viii. Operational.
      ix. Litigation.
D. Specific Definitions for VM-22

**Buffer Annuity**
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

- **Deferred Income Annuity (DIA)**
  An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin one year 13 months or later after (or from) the issue date if the contract holder survives to a predetermined future age.

- **Fixed Indexed Annuity (FIA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, subject to certain limits, typically with guaranteed principal.

- **Flexible Premium Deferred Annuity (FPDA)**
  An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

- **Funding Agreement**
  A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

- **Guaranteed Investment Contract (GIC)**
  Insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

- **Index Credit Hedge Margin**
  A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

- **Index Credit**
  Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to the contract policy values that is linked to an index or indices. Amounts credited to the contract policy resulting from a floor on an index account are included.

---

Commented [X31]: It seems the definitions included in this section are largely only used for the purpose of establishing the scope in Section 2. Since this is intended to be a principles-based methodology, recommend a strong definition of “Fixed Annuity” instead of specific products underneath this business. The first paragraph in A. Scopes seems to provide this with specific references which are out of scope. If changing the scope section, we would suggest deleting the various product definitions if not used elsewhere; if these definitions are potentially applied beyond VM-22, we would suggest moving any necessary definitions to VM-01.

Commented [CD32]: The format of this Definitions section is inconsistent with other parts of the VM. In VM-01 and VM-21, each defined term is numbered, and is defined in this format (for example): 1. The term “buffer” is interchangeable with the term “registered index-linked annuity (RILA)”, as defined in Section 1.D.7.

Commented [X33]: The term Buffer Annuity is not interchangeable to Registered Indexed-Linked Annuity (RILA) since Buffer Annuity is a subset of RILA. RILA can have different downside protections such as “Buffer” or “Floor”. Recommend deleting Buffer Annuity or add definitions for Buffer Annuity as a subtype in the RILA definition.

Commented [X34]: Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.

Commented [X35]: The wording “after (or from)” the issue date used in the DIA and SPIA definitions is confusing. Recommend keeping it simple as “from” the issue date.

Commented [X36]: Is “typically” intended to be a requirement in the definition? That is, to qualify as FIA does there need to be guaranteed principle?

Commented [CD37]: insert: “subject to certain limits”.

Commented [X38]: The definition of FIA describes the account value as typically with guaranteed principal. Since FIA always has the guaranteed principal, recommend deleting the wording “typically”.

Commented [CD39]: should be “contract”.

Commented [CD40]: should be “contract”.
• **Index Crediting Strategy**
  The strategy defined in a contract to determine index credits for a contract. This process may involve underlying index, index parameters, date, timing, performance triggers, and other elements of the crediting method.

• **Index Parameter**
  Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

• **Longevity Reinsurance**
  An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

  Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

  Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

• **Market Value Adjustment (MVA) Annuity**
  An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

• **Modified Guaranteed Annuity (MGA)**
  A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account and the value of which is guaranteed if held for specified periods of time. The contract contains nonforfeiture values and death benefits that are based upon a market-value adjustment formula if held for shorter periods.

Commented [X41]: We would suggest adding performance trigger to the list, along with other potential crediting methods; alternatively, the definition could specify that the crediting methods listed are examples only.

Commented [X42]: The definition states that “Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition”. Why is this the case and does this imply that longevity swaps are not within the scope of VM-22? Recommend adding to the out of scope list in “2.A. Scope” if that is the case. Clarification would also be helpful on what guidance should be used for these agreements if out of scope for VM-22. Further, we would suggest removing “typically” from the definition.

Commented [VM2243R42]: Target resolving definition of longevity reinsurance prior to addressing NJ comment letter on using a potential net premium method.

Commented [VM2244]: New Jersey comment letter: due to future premiums, longevity reinsurance may generate negative reserves, which can be used to eliminate or reduce other immediate annuity reserves. Suggest using net premium methodology, solving for k-factor at issue to solve for PV(premiums) = PV(benefits).

Commented [VM2245R44]: Target resolving definition of longevity reinsurance prior to addressing NJ comment.
• **Multiple-Year Guaranteed Annuity (MYGA)**
  A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

• **Pension Risk Transfer (PRT) Annuity**
  An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

• **Registered Index-Linked Annuity (RILA)**
  An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

• **Single Premium Immediate Annuity (SPIA)**
  An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within 12 months, some years after (or from) the issue date.

• **Single Premium Deferred Annuity (SPDA)**
  An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.

• **Stable Value Contract**
  A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

• **Structured Settlement Contract (SSC)**
  A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

• **Synthetic Guaranteed Investment Contract (Synthetic GIC)**
Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the contract policyholder or plan trust.

- **Term Certain Payout Annuity**
  A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

- **Two-Tiered Annuity**
  A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.

The term “cash surrender value” means, for the purposes of these requirements, the amount available to the contract holder upon surrender of the contract. Generally, it is equal to the account value less any applicable surrender charges, where the surrender charge reflects the availability of any free partial surrender options. However, for contracts where all or a portion of the amount available to the contract holder upon surrender is subject to a market value adjustment, the cash surrender value shall reflect the market value adjustment consistent with the required treatment of the underlying assets. That is, the cash surrender value shall reflect any market value adjustments where the underlying assets are reported at market value, but it shall not reflect any market value adjustments where the underlying assets are reported at book value.

The term “guaranteed minimum death benefit” (GMDB) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount; or (ii) exceeds the minimum amount and is:

- increased by an amount that may be either specified by or computed from other policy or contract values; and

- has the potential to produce a contractual total amount payable on such death that exceeds the account value, or

- in the case of an annuity providing income payments, guarantees payment upon such death of an amount payable on death in addition to the continuation of any guaranteed income payments.

**E. Materiality**

The company shall establish a standard containing the criteria for determining whether an assumption, risk factor, or other element of the principle-based valuation has a material impact on the size of the reserve. This standard shall be applied when identifying material risks.

**Section 2: Scope and Effective Date**
A. Scope

Subject to the requirements of this Sections 1 to 13 of VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
2. GIICs
3. Synthetic GIICs
4. Stable Value Contracts
5. Funding Agreements

Products in scope of VM-22 include non-variable-based annuities which consist of, but are not limited to, the following list:

- Account Value Based Annuities
  1. Deferred Annuities (SPDA & FPDA)
  2. Multi-Year Guarantee Annuities (MYGA)
  3. Fixed Indexed Annuities (FIA)
  4. Market, Value Adjustments (MVA)
  5. Two-tiered Annuities
  6. Guarantees/Benefits/Riders on Non-Variable-Based Annuity Contracts

- Payout Annuities
  1. Single Premium Immediate Annuities (SPIA)
  2. Deferred Income Annuities (DIA)
  3. Term Certain Payout Annuities
  4. Pension Risk Transfer Annuities (PRT)
  5. Structured Settlement Contracts (SSC)
  6. Longevity Reinsurance

Products out of scope include:

1. Contracts or benefits that are subject to VM-21 (such as variable annuities and RILAs)
2. GIICs
3. Synthetic GIICs
4. Stable Value Contracts
5. Funding Agreements

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.F. of VM-22.

B. Effective Date & Transition

Effective Date

These requirements apply for valuation dates on or after January 1, 2024.
Transition

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the first three years following the effective date of VM-22 PBR. If a company during the three-year transition period elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.

Commented [X84]: Need to clarify what is meant by “VM-22 PBR Requirements”. Add specific section references, or update proposal to have the PBR and non-PBR sections of this VM-22 draft in different chapters. After having reviewed, we think it would be much more clear to reconsider the use of “VM-23” for the PBR requirements to avoid ambiguity around scope/exclusions. The non-PBR sections also just don’t seem to fit in this draft, and there is now ambiguity around whether other parts of VM-22 apply to them (scope, effective date, principles, etc.).

Commented [X85]: To be more clear, recommend adding “transition period” to “the three years”.

Commented [X86]: Can a company wait until the end of the transition period to start PBR, but then apply PBR to the issues from during the transition period? This was unclear for VM-20, and still seems unclear here. Need to be explicit one way or the other.

Commented [CD87]: Will we (or should we) allow for any early adopters (like we did for VM-21)? It would seem reasonable to us to consider accommodating early adopters.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve ($SR$) (following the requirements of Section 4) plus the additional standard projection amount (following the requirements of Section 6) plus the DR for those contracts satisfying the Deterministic Certification Option, less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

Guidance Note: Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves ($SR$s), per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined: The Additional Standard Projection Amount

D. The Stochastic Reserve

The additional standard projection amount is determined by applying one of the two standard projection methods defined in Section 6. The same method must be used for all contracts within a group of contracts that are aggregated together to determine the reserve. The company shall elect which method they will use to determine the additional standard projection amount. The company may not change that election for a future valuation without the approval of the domiciliary commissioner.

D. The SR

1. The SR shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.G.

2. The stochastic reserve ($SR$) amount for any group of contracts shall be determined as $CTE_{70}$ of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve ($DR$) following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles: $SR$

Commented [X88]: Reinstate and modify later as needed - SPA being developed in separate workflow.

Commented [X89]: One of the most confused parts of the draft was referring to a DR as the SR for certain contracts. Need to handle and refer to separately.

Commented [X90]: Guidance is needed on how a pre-reinsurance reserve is to be determined.

Commented [X91]: Reinstate and modify later as needed - SPA being developed in separate workflow.

Commented [CD92]: Should this be Section 3.G?

Commented [X93]: Recommend replacing “the scenario reserve” with “the deterministic reserve”. Note that we also disagree with calling the deterministic reserve a stochastic reserve (later in draft), which adds a good deal of confusion.
a. Aggregate in a manner that is consistent with the company’s risk management strategy and reflect the likelihood of any change in risk offset that could arise from shifts between product types, and

b. Using prudent actuarial judgment, consider the following elements when aggregating groups of contracts: whether groups of contracts are part of the same portfolio (or different portfolios that interact), same integrated risk management system, administered managed together

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

5. To the extent that these limits on the aggregation results in more than one model segment, the stochastic reserve \( SR \) shall equal the sum of the stochastic reserve \( SR \) amounts computed for each model segment and scenario reserve \( DR \) amounts computed for each model segment for which the company elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test

1. To the extent that certain groups of contracts pass one of the predefined stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology pursuant to applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for immediate annuities specified in Section 13.

a. For dividend-paying contracts, a dividend liability shall be established following requirements in VM-A and VM-C, as described above, for the base contract.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018, AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on/after 2018; Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contracts company may not group together contract types with significantly different risk profiles when performing the exclusion tests should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserves in Section D above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements using the method outlined in Section 4.2.13, with the exception of contract following Section 3.E which are to be calculated on a seriatim basis.

G. Prudent Estimate Assumption:

1. With respect to the Stochastic Reserve \( SR \) in Section 3.D.C, the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements

Commented [X94]: As we have seen with VM-20, these types of extremely fuzzy requirements lead to full aggregation. If full aggregation is the intent, just explicitly allow it. We do recommend granular disclosures of the aggregation benefit for FIAs w/o GLBs, FIAs w/o GLBs, FIAs w/o GLBs, FIAs w/o GLBs, SPIAs, SELECT, TOL, and SSIC.

Commented [VM225]: In addition, consider full comment letter about longevity reinsurance, and how this fits into the above categories.

Commented [X96]: The term “Deterministic Certification Option” may be confusing, as there is no “deterministic” reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the wording to “with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E.”

Commented [X97]: Recommend replacing “the scenario reserve” with “the deterministic reserve.” Note that we also disagree with calling the deterministic reserve a stochastic reserve (later in draft), which adds a good deal of confusion.

Commented [CD98]: Suggest expanding header to “Stochastic Exclusion Test,” for clarity.

Commented [X99]: Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest rates should be broader, if even necessary. Suggest editing as:

These groups of contracts may be valued using the methodology and statutory maximum valuation rate.

Commented [CD100]: Suggest rewording to just say “the stochastic exclusion test”. There is only 1 STP, with 34 others.

Commented [X101]: Typos. Delete for clarity.

Commented [X102]: We believe this guidance note is unnecessary as the intent of the section is clear, and

Commented [X103]: The statement in this section is not acceptable as discussed in the previous TX comment.

Commented [X104]: This section seems to indicate that the grouping of contracts in exclusion testing should

Commented [CD105]: For clarity, change this reference to “Section 3.D.”

Commented [CD106]: Again, suggest rewording this to just say “the stochastic exclusion test”.

Commented [X107]: Based on VM-20 language.

Commented [X108]: Either in this item or in Section 12 allocation to contracts not covered by PBR methodology

Commented [X109]: This sub-section seems more appropriate in Section 4 or pulled out completely.

Commented [CD110]: VM-21 Section 3.H on simplifications, approximations, and modeling efficiency.

Commented [CD111]: Should this be “Section 3.D.”
in Section 12 of Model #820 and must periodically at least every 3 years review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary of the company shall set a new, adequate, anticipated experience assumption for the factor.

3. To determine the prudent estimate assumptions, the stochastic reserve SR shall also follow the requirements in Sections 4 and general assumptions including Section 9 for asset assumptions, Section 10 for contract policy holder behavior assumptions, and Section 11 for mortality assumptions, and Section 12 for general guidance and expense assumptions.

H. A company may use simplifications, approximations, and modeling efficiency techniques to calculate the SR and/or the additional standard projection amount required by this section if the company can demonstrate that the use of such techniques does not understate the reserve by a material amount, and the expected value of the reserve calculated using simplifications, approximations, and modeling efficiency techniques is not less than the expected value of the reserve calculated that does not use them.

Guidance Note:

Examples of modeling efficiency techniques include, but are not limited to:

1. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters.

2. Generating a smaller liability or asset model to represent the full seriatim model using grouping compression techniques or other similar simplifications.

There are multiple ways of providing the demonstration required by Section 3.H. The complexity of the demonstration depends upon the simplifications, approximations or modeling efficiency techniques used. Examples include, but are not limited to:

1. Rounding at a transactional level in a direction that is clearly and consistently conservative or is clearly and consistently unbiased with an obviously immaterial impact on the result (e.g., rounding to the nearest dollar) would satisfy 3.H without needing a demonstration. However, rounding to too few significant digits relative to the quantity being rounded, even in a unbiased way, may be material and in that event, the company may need to provide a demonstration that the rounding would not produce a material understatement of the reserve.

2. A brute force demonstration involves calculating the minimum reserve both with and without the simplification, approximation or modeling efficiency technique, and making a direct comparison between the resulting reserve. Regardless of the specific simplification, approximation or modeling efficiency technique used, brute force demonstrations always satisfy the requirements of Section 3.H.
3. Choosing a reduced set of scenarios from a larger set consistent with prescribed models and parameters and providing a detailed demonstration of why it did not understage the reserve by a material amount and the expected value of the reserve would not be less than the expected value of the reserve that would otherwise be calculated. This demonstration may be a theoretical, statistical or mathematical argument establishing, to the satisfaction of the insurance commissioner, general bounds on the potential deviation in the reserve estimate rather than a brute force demonstration.

4. Justify the use of randomly sampling withdrawal ages for each contract instead of following the exact prescribed WDCM method by demonstrating that the random sampling method is materially equivalent to the exact prescribed approach, and the simplification does not materially reduce the Additional Standard Projection Amount and the final reported reserve. In particular, the company should demonstrate that the statistical variability of the results based on the random sampling approach is immaterial by testing different random sets, e.g., if randomly selecting a withdrawal age for each contract, the probability distribution of the withdrawal age should be stable and not vary significantly when using different random number sets.

Commented [X119]: Specific example should be tailored based on the SPA developed.

Commented [X120]: Added consistent with VM:21 Section 3.H, which was added to the 2022 VM.
Section 4: Determination of Stochastic Reserve SR

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Sections 4 and 9.D. The company shall project cash flows including the following:

a. **Revenue** — Gross premiums received by the company including gross premiums received from the policyholder, policyholder (including any due premiums as of the projected start date).

**Guidance Note:** If due premiums are modeled, the final reported reserve needs to be adjusted by adding the due premium asset.

b. Other revenues, including contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).

c. All material benefits projected to be paid to policyholders—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts associated with business in force as of the valuation date.

**Guidance Note:** Amounts charged to account values on general account business are not revenue; examples include rider charges and expense charges.

ad. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.IJ.

be. Insurance company expenses (including overhead and investment maintenance expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses) other acquisition expenses associated with business in force as of the valuation date.

dg. Cash flows from hedging instruments as described in Section 4.A.4.

eh. Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains, and other expenses.
gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.

Guidance Note: Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance).

Guidance Note: Section 4.A.1 requires market value adjustments (MVAs) on liability cash flows to be reflected because in a cash flow model, assets are assumed to be liquidated at market value to cover the cash outflow of the cash surrender; therefore, inclusion of the market value adjustment aligns the asset and liability cash flows. This may differ from the treatment of MVAs in the definition of cash surrender value (Section 1.D), which defines the statutory reserve floor for which the values must be aligned with the annual statement value of the assets.

2. Grouping of Index Crediting Strategies

Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

3. Model Cells

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.

4. Modeling of Hedges
a. For a company that does not have a future hedging program tied directly to supporting the contracts falling under the scope of VM-22 stochastic reserve SR requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

b) No hedge positions in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program tied directly to supporting the contracts falling under the scope of VM-22 stochastic reserve SR requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders.

b) Existing hedging instruments that are currently held by the company for this purpose should be modeled consistently with the requirements of Section 4.A.4.a.ii.

c) An Index Credit Hedge Margin for these hedge instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible company experience and be no less than [X%] multiplicatively of the historical value of the index.

Commented [X135]: Suggest rewording "future hedging program" to "hedging program with future transactions" to avoid ambiguity.

Commented [CD136]: The word "future" to describe the "hedging program" here is confusing. What about current hedging programs with expected future hedge purchases? Why not just say "hedging program"? Also, I wanted to note that removing the concept of CDHS creates inconsistency with both VM-20 and VM-21. Why not retain it?

Commented [CD137]: same comment as above, about the word "future" being confusing.

Commented [CD138]: "contract holders"

Commented [X139]: "Any other purpose" in the last sentence seems overly broad and should be narrowed.

Commented [X140]: Specify "for this purpose" as "for offsetting the indexed credits", specify "for any other purposes" as "not for offsetting the indexed credits".

Commented [X141]: We believe the company should determine the appropriate margin based on their demonstration of effectiveness. Any guardrails on these undetermined values should be minimal, including as low as 0, subject to the appropriate demonstration of effectiveness. Further, we believe that documentation of effective product management should be contemplated in addition to historical effectiveness.

Commented [CD142]: clarify verbiage by saying "hedge instruments" or "derivative instruments"
the interest credited. In the absence of sufficient and credible company experience, a margin of [\%] shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than [\%]. It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve SR.

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future. Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve SR as the weighted average of two CTE values; first, a CTE70 ("best efforts") representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE70 ("adjusted") which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i., if the company has an indexed credit hedging program, the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.ii.c, in both the "best efforts" run and the "adjusted" run.

d) The use of products not falling under the scope of Section 1 through 13 requirements (e.g., variable annuities) as a hedge shall not be recognized in the determination of accumulated deficiencies.

Guidance Note: Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other fixed income assets supporting the contracts, and a margin is reflected rather than modeling using...
a CTE70 adjusted run with no future hedge purchases. If a company has a more comprehensive hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or economic hedging), an appropriate and documented bifurcation method should be used in the application of sections 4.A.4.b.i and 4.A.4.b.ii above for the hedge modeling and justification. Such bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

**Guidance Note:** The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.

5. **Revenue Sharing**

   If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each of the requirements set forth in VM-21 Sections 4.A.5.a through 4.A.5.f are met.

6. **Length of Projections**

   Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods obligations remain at the end of the projection periods. Company can choose to run a shorter projection period but not shorter than 20 years and include the present value of the terminal benefits and expenses in the accumulated deficiency calculation.

7. **Interest Maintenance Reserve (IMR)**

   The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

**B. Determination of Scenario Reserve**

1. For a given scenario, the scenario reserve shall be determined using one of two methods described below:

   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defasement of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period.

**Guidance Note:** The greatest present value of accumulated deficiencies can be negative.
The scenario reserve for any given scenario shall not be less than the cash surrender value with market value adjustment in aggregate on the valuation date for the group of contracts modeled in the projection.

2. Discount Rates

In determining the scenario reserve, unless using the direct iteration method pursuant to Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

a. The additional invested asset portfolio for a scenario is a portfolio of general account assets as of the valuation date, outside of the starting asset portfolio, that is required in that projection scenario so that the projection would not have a positive accumulated deficiency at the end of any projection year. This portfolio may include only (i) General Account assets available to the company on the valuation date that do not constitute part of the starting asset portfolio; and (ii) cash assets.

Guidance Note:
Additional invested assets should be selected in a manner such that if the starting asset portfolio were revised to include the additional invested assets, the projection would not be expected to experience any positive accumulated deficiencies at the end of any projection year.

It is assumed that the accumulated deficiencies for this scenario projection are known.

b. To determine the NAER on additional invested assets for a given scenario:

i. Project the additional invested asset portfolio as of the valuation date to the end of the projection period,

a) Investing any cash in the portfolio and reinvesting all investment proceeds using the company’s investment policy.

b) Excluding any liability cash flows.

c) Incorporating the appropriate returns, defaults and investment expenses for the given scenario.

ii. If the value of the projected additional invested asset portfolio does not equal or exceed the accumulated deficiencies at the end of each projection year for the scenario, increase the size of the initial additional invested asset portfolio as of the valuation date, and repeat the preceding step.

iii. Determine a vector of annual earned rates that replicates the growth in the additional invested asset portfolio from the valuation date to the end of the projection period.
projection period for the scenario. This vector will be the NAER for the
given scenario.

iv. If the depletion of assets within the projection results in an unreasonably
high negative NAER upon borrowing, the NAER may be set to the
assumed cost of borrowing associated with each projected time period, in
accordance with Section 4.D.3.c, as a safe harbor.

Guidance Note: There are multiple ways to select the additional invested asset portfolio at the valuation
date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent
in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

The number of scenarios for which the scenario reserve shall be computed shall be the
responsibility of the company, and it shall be considered to be sufficient if any resulting
understatement in the stochastic reserve $SR$, as compared with that resulting from running
additional scenarios, is not material.

2. Economic Scenario Generation

Treasury Department interest rate curves, as well as investment return paths for index
funds, equities, and fixed income assets shall be determined on a stochastic basis using the
methodology described in Section 8. If the company uses a proprietary generator to develop
scenarios, the company shall demonstrate that the resulting scenarios meet the
requirements described in Section 8.

D. Projection of Assets

1. Starting Asset Amount

a. For the projections of accumulated deficiencies, the value of assets at the start of
the projection shall be set equal to the approximate value of statutory reserves at
the start of the projection plus the allocated amount of PIMR attributable to the
assets selected. Assets shall be valued consistently with their annual statement
values. The amount of such asset values shall equal the sum of the following items,
all as of the start of the projection:

i. Any hedge instruments held in support of the contracts being valued; and

ii. An amount of assets held in the general account equal to the approximate
value of statutory reserves as of the start of the projections less the amount
in (i).

b. If the amount of initial general account assets is negative, the model should reflect
a projected interest expense. General account assets chosen for use as described

Commented [X160]: The wording "unreasonably high" is
not clear or appropriate. Recommend this requirement be
revised as part of a holistic fix to address extreme outliers in
NAER both on the low and high side to handle anomalies for
all of VM-20, VM-21, and VM-22. Some upper/lower cutoffs
could be used that depend on scenario returns.

Commented [CD161]: "unreasonably high" is not well
defined. Also, do we need to consider guardrails in the case
of "unreasonably high" positive NAERs, not just negative
NAERs?
above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets

For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

**Guidance Note:** Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets

a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:

i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;

ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the company’s investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results

Commented [X162]: This change was adopted for VM-20 and VM-21 for the 2022 VM.
in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the aggregate reserve shall be the higher of that produced by the modeled company investment strategy and any non-prescribed asset spreads shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained 'produced' by substituting an alternative investment strategy in which modeled fixed income reinvestment assets have the same weighted average life (WAL) as the reinvestment assets in the modeled company investment strategy and are all public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 20% PBR credit rating 3 (Aa2/AA)

iii. 60% PBR credit rating 6 (A2/A)

iv. 40% PBR credit rating 9 (Baa/BBB)

c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.i and Section 4.D.4.a.v, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.

Guidance Note: This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:

Commented [CD163]: should this be “stochastic reserve”, since this is within Section 4: Determination of Stochastic Reserve

Commented [X164]: This change was adopted for VM-20 and VM-22 for the 2022 VM.

Commented [CD165]: Suggest making this plural (“Treasuries”) to be consistent with Section 13.B.9

Commented [X166]: The proposed reinvestment mix comes from a different assumption context in current VM 22, i.e., it is designed to calculate the maximum allowed valuation interest rates, while the reinvestment mix for VM 22 PBR draft is to put a guardrail around the fixed income reinvestment assets. A guardrail is not intended to identify outliers and should not be tied to an average. The biggest concern is with the higher allocation percentage in BBB assets. The valuation manual should build an appropriate level of conservatism in the valuation standards instead of reflecting industry trends. By moving from VM-20 and VM-21 required mix of 50%/50% A/A to the proposed mix, the gross spreads increased by 20-30 bps for almost all WAL. We do not object to using a lower credit quality guardrail to get rid of any excessive conservatism. We recommend considering and comparing with other alternative allocations, something between the current and the proposed, e.g., 20% AA and 80% A. This will help regulators make informed decisions. In any case, we should be consistent with VM-20 and VM-21. If a change is made, it needs to be for all three.

Commented [CD167]: These references should be Section 4.D.3.a.ii and 4.D.3.a.v.
i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F as noted in 4.a.ii above.

b. Cash flows from general account-index funds and general account equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.H.

E. Projection of Annuitization Benefits

1. Assumed Annuitization Purchase Rates

a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such purchase rates shall reflect the payout rate specified in the contract.

b. For purposes of projecting future elective annuitization benefits (including annuitizations stemming from the election of a GMIB) and withdrawal amounts from GMWBs, the projected annuitization purchase rates shall be determined...
assuming that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuity Options

a. For contracts projected to elect future annuitization options (including annuitizations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections shall assume the contract will stay in force, the projected periodic payments are paid, and the associated maintenance expenses are incurred.

F. Frequency of Projection and Time Horizon

1. Use of an annual cash-flow frequency (“timestep”) is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

Care must be taken in simulating fee income and expenses when using an annual time step. For example, recognizing fee income at the end of each period after market movements, but prior to persistency decrements, would normally be an inappropriate assumption. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

Guidance Note: As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs

When determining a stochastic reserve, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve, additional standard projection amount the SR, DR, and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both a post-reinsurance ceded and a pre-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

Reflection of Reinsurance Cash Flows in the DR or SR

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve, SR and DR shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

i. In this section, reinsurance includes retrocession, and assuming company includes retrocessionaires.

ii. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

iii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iv. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the stochastic aggregate reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum aggregate reserve by the absolute value of such reductions in surplus.
b. In order to determine the stochastic reserve \( SR \) and \( DR \) on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve \( SR \) and \( DR \) shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard coinsurance treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection based on using starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable method.

**Guidance Note:** For standard pro rata insurance treaties (those that do not include experience refunds, where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld coinsurance; modified coinsurance; coinsurance with a trust. To the extent these assets would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard coinsurance treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

**Guidance Note:** Section 3.5.2 in ASOP No. 52, *Principle-Based Reserves for Life Products under the NAIC Valuation Manual*, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsurance policies belong and reflect the terms of the reinsurance agreement.

d. The company shall assume that the counterparties to a reinsurance agreement are knowledgeable about the contingencies involved in the agreement and likely to exercise the terms of the agreement to their respective advantage, taking into account the context of the agreement in the entire economic relationship between the parties. In setting assumptions for the NGE in reinsurance cash flows, the company shall include, but not be limited to, the following:

   i. The usual and customary practices associated with such agreements.
   ii. Past practices by the parties concerning the changing of terms, in an economic environment similar to that projected.
   iii. Any limits placed upon either party’s ability to exercise contractual options in the reinsurance agreement.
   iv. The ability of the direct-writing company to modify the terms of its policies in response to changes in reinsurance terms.
   v. Actions that might be taken by a party if the counterparty is in financial difficulty.

3. Reserve Determined Upon Passing the Exclusion Test
If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance-ceded and post-reinsurance-ceded reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance-ceded reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance-ceded reserves might not, or vice versa.

4. Additional Standard Projection Amount

Where reinsurance is ceded, the additional standard projection amount shall be calculated as described in Section 6 to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties. The additional standard projection amount shall also be calculated pre-reinsurance ceded using the methods described in Section 6 but ignoring the effects of the reinsurance ceded.
Section 6: To Be Determined

Commented [VM22196]: NY Comment Letter: Current CARVM standards should be a minimum floor for VM-22 policies, and only the stochastic reserve should permit grouping whereas the minimum floor should be seriatim.

Commented [X197]: SPA Section placement here still makes sense, but SPA under development.

Commented [VM22198]: Refer to equitable comment letter, which expresses support for the standard projection amount as a binding floor, with the suggestion to rely on company-specific assumptions for insignificant assumptions that are difficult to develop.
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve SR calculation if the stochastic exclusion test (SET) is satisfied for the each of the group of contracts. The company has the option to calculate or not calculate the SET.

   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then for each group of contracts that passes the SET, the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups of contracts. If the reserve methodology described in Section 4 is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.

   c. A company may not exclude a group of contracts from the stochastic reserve SR requirements if there are one or more future hedging programs associated with the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9.A.1.

B. Requirement to Pass the Types of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

1. Stochastic Exclusion Ratio Test (SERT)—Annually within 12 months before the valuation date, within 12 months before the valuation date the company demonstrates that the groups of contracts pass the SERT defined in Section 7.C.

2. Stochastic Exclusion Demonstration Test—In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.

3. SET Certification Method—For groups of contracts that do not have guaranteed living benefits, future hedging programs, or pension risk transfer business, in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts is not subject to material aggregate risk levels across interest rate risk, mortality and/or longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

Guidance Note: The qualified actuary should develop documentation to support the actuarial certification that presents his or her analysis clearly and in detail sufficient for another actuary to understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not subject to material interest rate risk, mortality and/or longevity risk, or asset return volatility risk.
Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:

a) A demonstration that, using requirements under VM-A and VM-C for the group of contracts, reserves calculated using requirements under VM-A and VM-C are at least as great as the assets required to support the group of contracts and certificates using the company’s cashflow testing model under each of the 4418 scenarios identified in this section or alternatively each of the New York seven economic scenarios, under each of the three mortality adjustment factors identified in Section 7.C.1.

b) A demonstration that the group of contracts passed the SERT within 36 months prior to the valuation date and the company has not had a material change in its interest rate risk, mortality and/or longevity risk, or asset return volatility risk.

c) A qualitative risk assessment of the group of contracts that concludes that the group of contracts does not have material interest rate risk, mortality and/or longevity risk, or asset return volatility. Such assessment would include an analysis of product guarantees, the company’s non-guaranteed elements (NGEs) policy, assets backing the group of contracts, the company’s longevity risk, and the company’s investment strategy.

C. Stochastic Exclusion Ratio Test

1. In order to exclude a group of contracts from the stochastic reserve SR requirements under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of \( \frac{b-a}{a} \) is less than the greater of \([\%]\) where and the percentage change that would trigger the company’s materiality standard, where:

   a. \( a \) = the adjusted scenario reserve described in Paragraph 7.C.2.a below using economic scenario \( \Phi_{\text{base}} \) and 100\% as the adjustment factor for mortality, the baseline economic scenario, as described in Appendix 1.E of VM-20.

   b. \( b \) = the largest adjusted scenario reserve described in Paragraph 7.C.2.b below under any of the other 4416 economic scenarios described in Appendix 1.E of VM-20 under [95\%], [90\%], [85\%], and [80\%] of anticipated experience mortality excluding margins. Because mortality variability may differ by company, if the magnitude of the company’s margin for mortality exceeds 5\%, then the company shall use the baseline mortality and the mortality augmented by plus and minus the company’s margin for this exercise.

Guidance Note: Note that the numerator should be the largest adjusted scenario reserve for scenarios other than the baseline economic scenario, minus the adjusted scenario reserve for the baseline economic scenario, and 100\% as the adjustment factor for mortality. This is not necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100\% as the adjustment factor for mortality, or the absolute value of the biggest difference from the adjusted scenario reserve for the baseline economic scenario and 100\% as the adjustment factor for mortality, both of which could lead to an incorrect test result.
There are 47 (=16x3-1) combined economic and mortality scenarios that should be compared for the determination of b.

2. In calculating the ratio in subsection (Section 7.C.1) above:
   a. The company shall calculate an adjusted scenario reserve for the group of contracts for each of each of the 16 scenario economic scenarios using the three levels of mortality adjustment factors that is equal to either (i) or (ii) below:
      i. The scenario reserve defined in Section 4, but with the following differences:
         a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph Section 7.C.1.b of this section.
         b) Using the interest rates and equity return assumptions specific to each scenario.
         c) Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.
         d) Shall reflect future mortality improvement in line with anticipated experience assumptions.
         e) Shall not reflect correlation between longevity and economic risks.
      ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:
         a) Using the interest rates and equity return assumptions specific to each scenario.
         b) Using the mortality scalars described in Paragraph Section 7.C.1.b of this section.
         c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.
   b. The company shall use the most current available baseline economic scenario and the 15 other economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.
   c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.
   d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.
e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the stochastic exclusion ratio test unless only a pre-reinsurance ceded basis upon determining the pre- or post-reinsurance reserve-ceded aggregate reserve.

### 3.
If the ratio calculated in this section is less than \([x]\)% pre-non-proportional reinsurance, but is greater than \([x]\)% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation • SERT = the ratio \((b-a)/a\) defined in Section 7.C.1 above

   a) The pre-non-proportional reinsurance results are “gross of non-proportional,” with a subscript “gn,” so denoted SERT\(_{gn}\)

   b) The post-non-proportional results are “net of non-proportional,” with subscript “nn,” so denoted SERT\(_{nn}\)

ii. If a block of business being tested is subject to one or more non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurances but ignoring the non-proportional contract(s), and “net of non-proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.

iii. So, if SERT\(_{gn}\) ≤ \([x]\)% but SERT\(_{nn}\) > \([x]\)%

   then compute the largest percent increase in reserve (LPIR) = \((b-a)/a\), both “gross of non-proportional” and “net of non-proportional.”

\[
\text{LPIR}_{gn} = \left(\frac{(b_{gn} - a_{gn})}{a_{gn}}\right)\left(\frac{a_{gn}}{a_{nn}}\right)
\]

\[
\text{LPIR}_{nn} = \left(\frac{(b_{nn} - a_{nn})}{a_{nn}}\right)\left(\frac{a_{nn}}{a_{nn}}\right)
\]

Note that the scenario underlying \(b_{nn}\) could be different from the scenario underlying \(b_{nn}\).

If SERT\(_{gn}\) × LPIR\(_{nn}\)/LPIR\(_{gn}\) ≤ \([x]\)%

then the block of contracts passes the SERT.

b. Another more qualitative approach is to adjust the calculated scenario reserves for the 1648 combined economic and mortality scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.
4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section of Section 7.D.2/a or Section 7.D.2/b and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve SR requirements using the methodology in this section Stochastic Exclusion Demonstration Test, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:
   a. The demonstration shall provide a reasonable assurance that if the stochastic reserve SR was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve SR exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve SR requirements.
   b. If, as of the end of any calendar year, the company determines the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.
   c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an explanation of why the use of such a date will not produce a material change in the outcome, as compared to results based on an analysis as of the valuation date.
   d. The demonstration shall provide an effective evaluation of the residual risk exposure remaining after risk mitigation techniques, such as derivative programs and reinsurance.

2. The company may use one of the following or another method acceptable to the insurance commissioner to demonstrate compliance with subsection Section 7.D.1 above:
   a. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve SR calculated on a stand-alone basis.
   b. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the scenario reserve that results from each of a sufficient number of adverse deterministic scenarios.
c. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C is greater than the stochastic reserve SR calculated on a stand-alone basis, but using a representative sample of contracts in the stochastic reserve SR calculations.

d. Demonstrate that any risk characteristics that would otherwise cause the stochastic reserve SR calculated on a stand-alone basis to exceed the statutory reserve calculated in accordance with VM-A and VM-C, are not present or have been substantially eliminated through actions such as hedging, investment strategy, reinsurance or passing the risk on to the contract holder by contract provision.

E. Deterministic Certification Option

1. The company may choose to determine the stochastic reserve SR for a group of contracts using a single deterministic economic scenario, subject to the following conditions:

a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies contracts and certificates. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recurring premium payments, and guaranteed living benefits.

b. The company certifies that the group of policies contracts and certificates is not supported by a reinvestment strategy that contains future hedge purchases.

c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing the scenario reserve volatility across contracts. The company must pass the exclusion ratio test when considering only the 16 economic scenarios, paired with the 100% mortality scenario.

d. The company must disclose a description of contracts and associated features in the certification.

Drafting Note: Consider revisiting Paragraph E.1.e to possibly either require 1) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario; or ii) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve SR for the group of contracts under the Deterministic Certification Option is determined as follows:

a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).

b. The stochastic reserve SR equals the scenario reserve following the requirements for Section 4.
Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.

Commented [X269]: Recommend deleting guidance note, as it doesn’t provide full or clear scope of what may be excluded, so could be misread to either guarantee option for certain products or exclude the option for other products.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Non-Index Credit Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company only hedges index credits. If the company or (a) clearly separates index credit hedging from other hedging, then only the section only pertains to the other hedging if the index hedging follows. In these situations, the modeling of hedges supporting index credits can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.4.b.1.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the calculation of the stochastic reserve\[^{236}\], determined in accordance with Section 3.D and Section 4.D.

3. The company shall take into account the costs and benefits of hedge positions expected to be held by the company in the future along each scenario. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than [6] months. Including the hedging strategy, used to implement the investment policy.

4. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. This also is referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which also is referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

5. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve\[^{236}\] otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.

Commented [X270]: Section 4.A.4 (Modeling of Hedges) has some relationship with this section, we request clarification around the applicability of these two areas of hedge guidance.

Commented [CD271]: see previous comments about use of the word “future” to describe “hedging strategy”

Commented [X272]: We seek clarification of this text: if a company only hedges indices or separates index crediting from other hedges, does this apply, or does it only apply to any other hedging?

Commented [X273]: What is the relationship of the “hedge purchases”?

Commented [CD274]: is this a typo? should this be “purchases”?

Commented [X275]: This 6 month exclusion creates unintended optionality for inclusion/exclusion based on whether a hedge strategy is considered “new”. Instead, this should be addressed through the Error factor for new programs being temporarily larger.

Commented [X276]: Reinsert the original sentence which puts the reflection of hedging into the greater context of reflecting the company’s investment policy.

Commented [X277]: Agree that the uncertainty associated with new strategies should be handled via the E factor, not through blanket exclusion.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserveSR otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserveSR needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserveSR attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock-tested.

Guidance Note: No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

C. Calculation of Stochastic ReserveSR (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no future hedging purchases and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.1.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserveSR is given by:

\[ \text{Stochastic ReserveSR} = \text{CTE70 (best efforts)} + E \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}] \]
4. The company shall specify a value for $E$ (the “error factor”) in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of $E$. The value of $E$ may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, $E$ must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recent available relevant period of data (but no less than 12 months), to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for $E$.

6. Such a back-test shall involve one of the following analyses:

   a. For companies that model hedge cash flows directly (“explicit method”), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses—both realized and unrealized—observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g., reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

      To support the choice of a low value of $E$, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of $E$ by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

   b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an “implicit method” or “cost of reinsurance method”), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

      i. Determine the hedge asset gains and losses—both realized and unrealized—incurred over the month attributable to equity, interest rate, and implied volatility movements.

      ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).

Commented [X283]: We have been getting weak $E$ factor support, with minimum backtesting due to the current phrasing.

Commented [X282R281]: Recommend adding stress testing language similar to section 4.A.4.c.i.e) but with edits based on TDI’s comments/suggestions to Section 4.A.4.b.i.e).

Commented [X283]: Recommend adding reporting requirement to VM-31 to disclose if company has switched between explicit method and implicit method, discuss rationale of the change and the change impact.
iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.

iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with less than 6 months of history, E should be at least 1.0.50. However, E may be lower than 1.0.50 if at least 6 months of reliable experience is available and/or if the change in strategy is a minor refinement rather than a material change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).
Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program.

- The error factor should be temporarily large (e.g., > 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily 100% for material changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy).

- An increase in the error factor may not always be needed for minor refinements to the hedge strategy (e.g., moving from swaps to Treasury futures).

8. The company shall set the value of E reflecting the extent to which the future hedging program is clearly defined. To support a value of E below 1.0, there should be very robust documentation outlining the future hedging program. To the extent that documentation outlining the future hedging program is incomplete, the value of E shall be increased. Any increases required to the value of E to reflect that documentation is not available to support that the future hedging program is clearly defined shall be in addition to increases to the value of E to reflect a lack of historical experience or to reflect the back-testing results.

E. Additional Considerations for CTE70 (best efforts)

If the company is following a CDHS, the fair value of the portfolio of contracts falling within the scope of these requirements shall be computed and compared to the CTE70 (best efforts) and CTE70 (adjusted). If the CTE70 (best efforts) is below both the fair value and CTE70 (adjusted), the company should be prepared to explain why that result is reasonable.

For the purposes of this analysis, the SR and fair value calculations shall be done without requiring the scenario reserve for any given scenario to be equal to or in excess of the cash surrender value in aggregate for the group of contracts modeled in the projection.

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for purposes of reducing the stochastic reserve SR, the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions

Commented [X285]: Work is being done by the hedging DG. This is a placeholder. Need to reflect how clearly defined and well documented the hedge program is, to be able to rely on the backtesting provided. To the extent that hedge programs are not clearly defined, E should be increased to reflect that the backtesting cannot be relied on as an indicator of future effectiveness.

Commented [X286]: Reinstate this disclosure item, which is a rough reasonableness check for regulator review/information on the modeled hedge benefit and can prompt further discussion.

Commented [CD287]: Not sure why this section is being deleted? Perhaps references to CDHS could be deleted, but otherwise this section still seems applicable.
on future trading, transaction costs, other elements of the model, the strategy, the mix of
business and other items that are likely to result in materially adverse results. This includes
an analysis of model assumptions that, when combined with the reliance on the hedging
strategy, are likely to result in adverse results relative to those modeled. The parameters
and assumptions shall be adjusted (based on testing contingent on the strategy used and
other assumptions) to levels that fully reflect the risk based on historical ranges and
foreseeable future ranges of the assumptions and parameters. If this is not possible by
parameter adjustment, the model shall be modified to reflect them at either anticipated
experience or adverse estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the
sensitivities to equity markets and interest rates (commonly referred to as the Greeks)
associated with the guaranteed contract holder options embedded in the variable fixed
indexed annuities and other in-scope products and these same sensitivities associated with
the hedging assets are subject to material discontinuities. This includes, but is not limited
to, a hedging strategy where material hedging assets will be obtained when the fixed
indexed annuity and other in-scope products account balances reach a predetermined level
in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy,
can be a discontinuous hedging strategy if implementation of the strategy permits material
discontinuities between the sensitivities to equity markets and interest rates associated with
the guaranteed contract holder options embedded in the variable fixed indexed annuities
and other in-scope products and these same sensitivities associated with the hedging assets.
There may be scenarios that are particularly costly to discontinuous hedging strategies,
especially where those result in large discontinuous changes in sensitivities (Greeks)
associated with the hedging assets. Where discontinuous hedging strategies contribute
materially to a reduction in the stochastic reserve \( SR \), the company must evaluate the
interaction of future trigger definitions and the discontinuous hedging strategy, in addition
to the items mentioned in the previous paragraph. This includes an analysis of model
assumptions that, when combined with the reliance on the discontinuous hedging strategy,
may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that
depend on specific values of an index or other market indicators may not be implemented
as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial
actual market asset prices, prices for trading at future dates, transaction costs and other
assumptions—should be analyzed by the company as to whether the stochastic cash-flow
model permits hedging strategies that make money in some scenarios without losing a
reasonable amount in some other scenarios. This includes, but is not limited to:

a. Hedging strategies with no initial investment that never lose money in any scenario
and in some scenarios make money.

b. Hedging strategies that, with a given amount of initial money, never make less than
accumulation at the one-period risk-free rates in any scenario but make more than
this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be
satisfied that the results do not materially rely directly or indirectly on the use of such
strategies. If the results do materially rely directly or indirectly on the use of such strategies,
the strategies may not be used to reduce the stochastic reserve \( SR \) otherwise calculated.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the reserves level. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B and Section 12.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may or may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more material behavior assumptions, if relevant to the risks in the product, and thus the approach will not understate the reserve.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the company qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Account transfers.
- Future deposits.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently (but no less than every 3 years) when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
   b. Surrenders.
   c. Partial withdrawals (systematic and elective).
   d. Account transfers (switching/exchanges).
   e. Resets/ratchets of the guaranteed amounts (automatic and elective).
   f. Future deposits.
   g. Income start date for the benefit utilization.
   h. Commutation of benefit (from periodic payment to lump sum) or vice versa.

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions.
   For example:
   a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing, ) or if the contract provisions incentivize the contract holders to transfer between accounts.
   b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).
   c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

Guidance Note: For some non-elective benefits (nursing home benefits for example), unless relevant company experience exists to the contrary, the use of incidence rates greater than zero after the surrender charge has ended, or the cash value was depleted might be inappropriate may not be prudent since it would reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.
4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):
   a. Gender.
   b. Attained age.
   c. Issue age.
   d. Contract duration.
   e. Time to maturity.
   f. Tax status.
   g. Account value.
   h. Interest credited (current and guaranteed).
   i. Available indices.
   j. Guaranteed benefit amounts.
   k. Surrender charges, transaction fees or other contract charges.
   l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders' efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100%...

Commented [X307]: This also applies to VM-21, as there are fixed accounts. Is there any reason not to be consistent?

Commented [X308]: This is not a synonym (perhaps transfer fees is a subset of transaction fees) - why would transaction fees apply for VM-21, but only transfer fees for VM-22?

Commented [X309]: This section states that "contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally." This text seems to directly contradict Section II. Reserve Requirements 6.H.2 which states "When advantageous, policyholders will commence living benefit payouts if not started yet." We suggest revising 6.H.2 to align with the text of 10.D.8.
efficiency in a financially rational manner nor assume that contract holders will always act
irrationally. These extreme assumptions may be used for modeling efficiency if the result
is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability
model should incorporate margins for uncertainty for all risk factors that are not dynamic
(i.e., the non-scenario tested assumptions) and are assumed not to vary according to the
financial interest of the contract holderstochastically modeled.

2. The behavior assumptions should be logical and consistent both individually and in
aggregate, especially in the scenarios that govern the results. In other words, the company
should not set behavior assumptions in isolation, but give due consideration to other
elements of the model. The interdependence of assumptions (particularly those governing
customer behaviors) makes this task difficult and by definition requires professional
judgment, but it is important that the model risk factors and assumptions.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with
the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution).
To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the
model) in order to determine exactly which scenario results are included in the CTE
measure. Rather, in light of the products being valued, the company should be mindful of
the general characteristics of those scenarios likely to represent the tail of the loss
distribution and consequently use prudent estimate assumptions for behavior that are
reasonable and appropriate in such scenarios. For non-variablefixed annuities, these
“valuation” scenarios would typically display one or more of the following attributes:

   a. Declining, increasing and/or volatile index values, where applicable.
   b. Price gaps and/or liquidity constraints.
   c. Rapidly changing Volatile interest rates or persistently low interest rates.
   d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in
aggregate, especially in the scenarios that govern the results. In other words, the company
should not set behavior assumptions in isolation, but give due consideration to other
elements of the model. The interdependence of assumptions (particularly those governing
customer behaviors) makes this task difficult and by definition requires professional
judgment, but it is important that the model risk factors and assumptions.
a. Remain logically and internally consistent across the scenarios tested.

b. Represent plausible outcomes.

c. Lead to appropriate, but not excessive, asset requirements.

4. The company should remember that the continuum of “plausibility” should not be confined or constrained to the outcomes and events exhibited by historic experience.

5. Companies should attempt to track experience for all assumptions that materially affect their risk profiles by collecting and maintaining the data required to conduct credible and meaningful studies of contract holder behavior.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:
   a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.
   b. Complies with the contract holder behavior requirements stated in Section 10.A to Section 10.G above in this section.

2. If the company models policy loans explicitly, the company shall:
   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.
   b. Assign loan balances either to exactly match each policy's utilization or to reflect average utilization over a model segment or sub-segments if the results are materially similar.
   c. Model policy loan interest in a manner consistent with policy provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
I. Non-Guaranteed Elements

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy contract costs or values and are not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to non-variable fixed annuities include but are not limited to the following: index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollup rates, rollup period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.I.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of an NGE that:
   a. Is not based on some aspect of the policy’s or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

   However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude...
from its model any NGE that the board has guaranteed for future years, even if it
could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been
established according to statutory accounting principles as of the valuation date is reported
separately from the statutory reserve. The contract holder dividends that give rise to this
dividend liability as of the valuation date may or may not be included in the cash-flow
model at the company’s option.

   a. If the contract holder dividends that give rise to the dividend liability are not
      included in the cash-flow model, then no adjustment is needed to the resulting
      stochastic reserve.SR

   b. If the contract holder dividends that give rise to the dividend liability are included
      in the cash-flow model, then the resulting stochastic reserve.SR should
      be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations
and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the stochastic reserve. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances, and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management, and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from similar industries or geographies that may be used to sub-divide in-force blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to...
how payout annuities vs. deferred annuities are distinguished.

Guidance Note: Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.

4. Margin for Data Uncertainty

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) mortality (longevity) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a mortality (longevity) plus (minus) segment to a longevity (mortality) minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2 for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

Commented [X339]: Recommend deleting this guidance note since it is unnecessary - there is no such restriction for any of VM-20, VM-21 or VM-22. It would be an absurd level of granular distinction, such that it is not clear you could actually perform the projection, given that assumptions vary by attained age, etc.

Commented [X340]: Termining the segments "mortality (longevity) segments" would be easier to understand than "plus (minus) segments".

Commented [X341]: It is unclear how to interpretate the statement and how to review it for both VM-21 and VM-22. If a company reinsures GMWB riders, then does it mean that on a net basis the segment would no longer be considered as minus? So, there would be distinct designations for the pre and post reinsurance runs? Recommend discussing the statement and adding additional language or a guidance note to make it clear.

Commented [X342]: Delete period, it is a typo

Commented [X343]: Does this need to be edited to be consistent with "little or no" data?
i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:

\[ q_{x}^{20XX+n} = q_{x}^{20XX}(1 - G_{x})^{n} \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage \( F_{x} \) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual deferred annuities that do not contain guaranteed living benefits

\[ q_{x}^{2012+n} = q_{x}^{2012}(1 - G_{x})^{n} \times F_{x} \]

b. [1983 Table “a”] for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_{x}^{1994+n} = q_{x}^{1994}(1 - AA_{x})^{n} \]

### 4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

a. **Underreporting of Deaths**

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

b. **Experience by Contract Duration**

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by

iii. For a business segment with non-U.S. insureds, **when little or no experience or information is available on a business segment**, an established industry or national mortality table and mortality improvement scale may be used, with approval from the domiciliary commissioner.
1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves including margins for uncertainty with the mortality assumptions described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

Guidance Note: For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the industry mortality assumption described in Section 11.B.3 used in the blending.

2. Adjustment of Statutory Valuation Industry Mortality for Improvement

For purposes of the adjustment for credibility, the industry mortality table for a plus segment may be and the industry mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective industry mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.
b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.

f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve $SR$. If such an adjustment would reduce the stochastic reserve $SR$, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Other Guidance and Requirements for Assumptions

A. Overview
This section provides guidance and requirements in general for setting prudent estimate assumptions when determining either the SR or DR. It also provides specific guidance and requirements for expense assumptions.

B. General Assumption Requirements

1. The company shall use prudent estimate assumptions for risk factors that are not stochastically modeled by applying margins to the anticipated experience assumptions if such risk factors have been categorized as material risks by following Section 1.B Principle 3 and requirements in Section 12.C.

2. The company shall establish the prudent estimate assumptions for risk factors in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

3. The company shall model the following risk factors stochastically unless the company elects to stochastically model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.
   a. Interest rate movements (i.e., Treasury interest rate curves).
   b. Equity performance (e.g., Standard & Poor’s 500 index [S&P 500] returns and returns of other equity investments).

4. If the company elects to stochastically model risk factors in addition to the economic scenarios, the requirements in this section for determining prudent estimate assumptions for these risk factors do not apply.

Guidance Note: It is expected that companies will not stochastically model risk factors other than the economic scenarios, such as contract holder behavior or mortality, until VM-22 has more specific guidance and requirements available. Companies shall discuss with domiciliary regulators if they wish to stochastically model other risk factors.

5. The company shall use its own experience, if relevant and credible, to establish an anticipated experience assumption for any risk factor. To the extent that company experience is not available or credible, the company may use industry experience or other data to establish the anticipated experience assumption, making modifications as needed to reflect the circumstances of the company.
   a. For risk factors (such as mortality) to which statistical credibility theory may be appropriately applied, the company shall establish anticipated experience assumptions for the risk factor by combining relevant company experience with industry experience data, tables or other applicable data in a manner that is consistent with credibility theory and accepted actuarial practice.
b. For risk factors (such as utilization of guaranteed living benefits) that do not lend themselves to the use of statistical credibility theory, and for risk factors (such as some of the lapse assumptions) to which statistical credibility theory can be appropriately applied but cannot currently be applied due to lack of industry data, the company shall establish anticipated experience assumptions in a manner that is consistent with accepted actuarial practice and that reflects any available relevant company experience, any available relevant industry experience, or any other experience data that are available and relevant. Such techniques include:

   i. Adopting standard assumptions published by professional, industry or regulatory organizations to the extent they reflect any available relevant company experience or reasonable expectations.

   ii. Applying factors to relevant industry experience tables or other relevant data to reflect any available relevant company experience and differences in expected experience from that underlying the base tables or data due to differences between the risk characteristics of the company experience and the risk characteristics of the experience underlying the base tables or data.

   iii. Blending any available relevant company experience with any available relevant industry experience and/or other applicable data using weightings established in a manner that is consistent with accepted actuarial practice and that reflects the risk characteristics of the underlying contracts and/or company practices.

c. For risk factors that have limited or no experience or other applicable data to draw upon, the assumptions shall be established using sound actuarial judgment and the most relevant data available, if such data exists.

d. For any assumption that is set in accordance with the requirements of Section 12.B.5.c, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing and disclose the analysis performed to ensure that the assumption is set at the conservative end of the plausible range.

e. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

6. The company shall sensitivity test risk factors that are not stochastically modeled and examine the impact on the stochastic reserve. The company shall update the sensitivity tests periodically as appropriate. The company may update the tests less frequently, but no less than every 3 years, when the tests show less sensitivity of the stochastic reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company...
may perform sensitivity testing:

a. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.

b. Using data from prior periods.

Guidance Note: Sensitivity testing every risk factor on an annual basis is not required. For some risk factors, it may be reasonable, in lieu of sensitivity testing, to employ statistical measures for margins, such as adding one or more standard deviations to the anticipated experience assumption.

7. The company shall vary the prudent estimate assumptions from scenario to scenario within the stochastic reserve calculation in an appropriate manner to reflect the scenario-dependent risks.

C. Assumption Margins

The company shall include margins to provide for adverse deviations and estimation error in the prudent estimate assumption for each risk factor that is not stochastically modeled or prescribed, subject to the following:

1. The level of margin applied to the anticipated experience assumptions may be determined in aggregate or independently as discussed in Section 1.B Principle 3. It is not permissible to set a margin less toward the conservative end of the spectrum to recognize, in whole or in part, implicit or prescribed margins that are present, or are believed to be present, in other risk factors.

Risks that are stochastically modeled (e.g., interest rates, equity returns) or have prescribed margins or guardrails (e.g., assets, revenue sharing) shall be considered material risks. Other risks generally considered to be material include, but are not limited to, mortality, contract holder behavior, maintenance and overhead expenses, inflation and implied volatility. In some cases, the list of material risks may also include acquisition expenses, partial withdrawals, policy loans, annuitizations, account transfers and deposits, and/or option elections that contain an element of anti-selection.

2. The greater the uncertainty in the anticipated experience assumption, the larger the required margin, with the margin added or subtracted as needed to produce a larger Sr or DR than would otherwise result. For example, the company shall use a larger margin when:

   a. The experience data have less relevance or lower credibility.
   b. The experience data are of lower quality, such as incomplete, internally inconsistent or not current.
   c. There is doubt about the reliability of the anticipated experience assumption, such as, but not limited to, recent changes in circumstances or changes in company policies.
   d. There are constraints in the modeling that limit an effective reflection of the risk factor.
3. In complying with the sensitivity testing requirements in Section 12.B.6 above, greater analysis and more detailed justification are needed to determine the level of uncertainty when establishing margins for risk factors that produce greater sensitivity on the stochastic reserve.

4. A margin is permitted but not required for assumptions that do not represent material risks.

5. A margin should reflect the magnitude of fluctuations in historical experience of the company for the risk factor, as appropriate.

6. The company shall apply the method used to determine the margin consistently on each valuation date but is permitted to change the method from the prior year if the rationale for the change and the impact on the stochastic reserve is disclosed.

D. Expense Assumptions

1. General Prudent Estimate Expense Assumption Requirements

   In determining prudent estimate expense assumptions, the company:

   a. May spread certain information technology development costs and other capital expenditures over a reasonable number of years in accordance with accepted statutory accounting principles as defined in the Statements of Statutory Accounting Principles.

   Guidance Note: Care should be taken with regard to the potential interaction with the inflation assumption below.

   b. Shall assume that the company is a going concern.

   c. Shall choose an appropriate expense basis that properly aligns the actual expense to the assumption. If values are not significant, they may be aggregated into a different base assumption.

   Guidance Note: For example, death benefit expenses should be modeled with an expense assumption that is per death incurred.

   d. Shall reflect the impact of inflation.

   e. Shall not assume future expense improvements.

   f. Shall not include assumptions for federal income taxes (and expenses paid to provide fraternal benefits in lieu of federal income taxes) and foreign income taxes.

   g. Shall use assumptions that are consistent with other related assumptions.

   h. Shall use fully allocated expenses.

   Guidance Note: Expense assumptions should reflect the direct costs associated with the block of contracts being modeled, as well as indirect costs and overhead costs that have been allocated to the modeled contracts.

   i. Shall allocate expenses using an allocation method that is consistent across
company lines of business. Such allocation must be determined in a manner that is within the range of actuarial practice and methodology and consistent with applicable ASOPs. Allocations may not be done for the purpose of decreasing the stochastic reserve.

i. Shall reflect expense efficiencies that are derived and realized from the combination of blocks of business due to a business acquisition or merger in the expense assumption only when any future costs associated with achieving the efficiencies are also recognized.

Guidance Note: For example, the combining of two similar blocks of business on the same administrative system may yield some expense savings on a per unit basis, but any future cost of the system conversion should also be considered in the final assumption. If all costs for the conversion are in the past, then there would be no future expenses to reflect in the valuation.

k. Shall reflect the direct costs associated with the contracts being modeled, as well as an appropriate portion of indirect costs and overhead (i.e., expense assumptions representing fully allocated expenses should be used), including expenses categorized in the annual statement as “taxes, licenses and fees” (Exhibit 3 of the annual statement) in the expense assumption.

l. Shall include acquisition expenses associated with business in force as of the valuation date and significant non-recurring expenses expected to be incurred after the valuation date in the expense assumption.

m. For contracts sold under a new policy form or due to entry into a new product line, the company shall use expense factors that are consistent with the expense factors used to determine anticipated experience assumptions for contracts from an existing block of mature contracts taking into account:

i. Any differences in the expected long-term expense levels between the block of new contacts and the block of mature contracts.

ii. That all expenses must be fully allocated as required under Section 12.D.1.h above.

2. Margins for Prudent Estimate Expense Assumptions

The company shall determine margins for expense assumptions following Section 12.C.
Section 13: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The allocation shall be made separately for DR and SR. The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td>140</td>
<td></td>
</tr>
<tr>
<td>Allocation Basis for the excess of the Aggregate Reserve over the Cash Surrender Value</td>
<td>10</td>
<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>

Commented [X366]: This method only makes sense if done separately for the DR and SR.
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

### Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value

<table>

<tr>
<td>20</td>
<td>20</td>
<td>20</td>
<td>10.91</td>
<td>9.09</td>
<td>0.00</td>
<td></td>
</tr>
</tbody>
</table>

**Option 2: Actuarial Present Value Approach**

**B.** The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve $\text{SR}$ defined in Section 3.D.
   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows, as well as any cash flows that are scenario dependent.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.
   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve $\text{SR}$ defined in Section 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

### Comment explanations:

**Commented [X367]:** This method depends on the NAER, so would not work for companies that use direct iteration.

**Commented [X368]:** This could give an unstable allocation if there is an even mix of products with different risk profiles, so that the tail is populated with some scenarios where Product A does poorly and some where Product B does poorly. The single scenario will only reflect the riskiness of one of the products.

**Commented [X369]:** Not just the NAER, but the cashflows are also scenario dependent.

**Commented [CD370]:** "Section 3.D"

*Cash Surrender Value
**Guaranteed Lifetime Withdrawal Benefit

Guidance Note: The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 1314: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section, and all contracts not passing the SET covered by Sections 1 through 13 of VM-22, are covered Section 14 of VM-22:
   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

Guidance Note: For Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f and Section 1314.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:
   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 1314.A.2.d, Section 1314.A.2.e, Section 1314.A.2.f, Section 1314.A.2.g or Section 1314.A.2.h, the
company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 1314 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B) (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C) (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 1314.B.1.c above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   **Guidance Note:** If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.
3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.

4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her age last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 1314 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*

   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.
   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

      Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5 Y</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>90+</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>80–89</td>
<td>B</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>70–79</td>
<td>C</td>
<td>C</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>&lt; 70</td>
<td>D</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

2. Premium Determination Dates

a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d and A.2.e</td>
<td>Fixed payout annuities resulting from settlement options or annuizitions from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
<tr>
<td>A.2.g</td>
<td>Fixed income payment streams from CDAs, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
**Guidance Note:** For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

| A.2.i | Group annuity and related certificates | Date consideration is determined and committed to by contract holder |

**b. Immaterial Change in Consideration**

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

3. **Statutory Maximum Valuation Interest Rate**

   a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 1314.C.1) and its Premium Determination Date (Section 1314.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

   b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

   c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

   d. **Quarterly Valuation Rate:**

   For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

   \[ I_q = R + S - D - E \]

   Where:

   a. \( R \) is the reference rate for that Valuation Rate Bucket (defined in Section 1314.C.4);
   b. \( S \) is the spread rate for that Valuation Rate Bucket (defined in Section 1314.C.5);
   c. \( D \) is the default cost rate for that Valuation Rate Bucket (defined in Section 1314.C.6);
and

d. E is the spread deduction defined as 0.25%.

c. Daily Valuation Rate:

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[ I_d = I_q + C_{d-1} - C_q \]

Where:

a. \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b. \( C_{d-1} \) is the daily corporate rate (defined in Section 1314.C.7) for the business day immediately preceding the premium determination date; and

c. \( C_q \) is the average daily corporate rate (defined in Section 1314.C.8) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate \( (I_d) \) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4. Reference Rate

Reference rates are updated quarterly as described below:

a. The "quarterly Treasury rate" is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b. Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c. The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

5. Spread

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a. Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.I) effective for the calendar year in which the premium determination date falls.

6. Default costs for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 1314.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAMLCA0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAMLCA0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAMLCA0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAMLCA0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAMLCA0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAMLCA0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 1314.C.7.a].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 1314.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating Iq in Section 1314.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:

i. Bucket A:
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   b) Five-year certain only.

ii. Bucket B:
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   b) 10-year certain only.

iii. Bucket C:
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   c) 15-year certain only.

iv. Bucket D:
   a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
   b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for
individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step e.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

   a) Column 1 of Table 4 is identical to column 1 of Table 1.
   b) Column 2 of Table 4 is 50% of column 2 of Table 1.
   c) Column 3 of Table 4 is identical to column 2 of Table 4.
   d) Column 4 of Table 4 is 50% of column 3 of Table 1.
   e) Column 5 of Table 4 is identical to column 4 of Table 4.
   f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 3.4.A.2.i), the following apply:

a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

**Guidance Note:** Under some group annuity contracts, certificates may be purchased on different
b. In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

**Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.
Valuation Manual Section II | Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for non-variable (fixed) annuity contracts issued prior to 1/1/2024 are those requirements as found in VM-A and VM-C as applicable, with the exception of the minimum requirements for the valuation interest rate for single premium immediate annuity contracts, and other similar contracts, issued after Dec. 31, 2017, including those fixed payout annuities emanating from host contracts issued on or after Jan. 1, 2017, and on or before Dec. 31, 2017. The maximum valuation interest rate requirements for those contracts and fixed payout annuities are defined in Section 13 of VM-22, Statutory Maximum Valuation Interest Rates for Income Annuity Formulae Reserves.

D. Minimum reserve requirements for non-variable (fixed) annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 13 of VM-22.

The requirements in this section are still considered a part of PBR requirements and therefore are applicable to VM-G.

The below principles may serve as key considerations for assessing whether VM-21 or VM-22 requirements apply.

D. Minimum reserve requirements apply.

E. Index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for application of VM-22 requirements:

1. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.

2. Credits a rate of interest under the contract prior to the application of any market value adjustments that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

Minimum reserve requirements.
Index-linked or modified guaranteed annuity contracts or riders that do not satisfy either of the two conditions listed above criteria in Paragraph Section 2.E.1.i and Section 2.E.2 above and E.1.ii may be a key consideration for application of VM-21. Are issued on 1/1/2024 and later are those requirements as found in VM-21.

Commented [X381]: VM-21 specifically says “These requirements do not apply to contracts falling under the scope of VM-A-255: Modified Guaranteed Annuities; however, they do apply to contracts listed above that include one or more subaccounts containing features similar in nature to those contained in modified guaranteed annuities (MGAs) (e.g., market value adjustments).” Is this a contradiction?

Commented [X382]: Consistent with E above.
Subsection 6: Riders and Supplemental Benefits

Guidance Note: Designs of policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts, not subject to Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.
2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.
3. After issuance, the base policy or contract value or benefits are determined by referencing the rider or supplemental benefit features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

E. If a term life insurance rider on the named insured[s] on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is...
separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.

4.F. For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

4.G. Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve (for VM-20 and VM-22) or TAR (for VM-21) if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves (for VM-20 and VM-22) or reserves and TAR (for VM-21), using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.

"aggregate" referred to potential compounding of interest rate, longevity, or asset risk then this could be redrafted to clearly call out a 4th category of risk due to a combination of the first three. However, I think this is already implicitly covered.

---

Page 33: [20] Commented [CD218]  CA DOI  12/30/2021 4:15:00 PM

note, there is no insertion of "aggregate risk levels across" here, like there was above. (to be clear, i don't support adding it.)

Subject: Comments on ARCGW-Proposed Draft of VM-22: PBR for Non-Variable Annuities

General comments:

1. Need to change “policy/policies” to “contract/contracts” throughout the document. Similarly, “policyholder(s)” should be changed to “contract holder(s)”.
   a. The one exception is for the term “policy loan”, which we should keep.
2. Need to incorporate changes (as appropriate) from the most recently adopted version of the VM, including any APFs adopted since that last version of the VM.
3. Should there be an exercise to consider which changes herein should also be made to VM-21 and/or VM-20, for consistency purposes?
4. Need to double check all section references (perhaps not needed until we get closer to a final draft).
5. Need to double check usage of “aggregate reserve” vs. “stochastic reserve”.
6. Adding page numbers to future drafts would be very helpful.

Specific comments:

7. Detailed comments are embedded within the PDF of the exposure draft (appended to this cover letter).
July 16, 2021
Bruce Sartain, Chair
Valuation Manual (VM)-22 (A) Subgroup
Life Actuarial (A) Task Force
National Association of Insurance Commissioners (NAIC)

Dear Mr. Sartain,

The American Academy of Actuaries\(^1\) Annuity Reserves and Capital Work Group (ARCWG) presented a fixed annuity principle-based reserving (PBR) framework proposal to the VM-22 Subgroup during its October 21, 2020 meeting. This document provides ARCWG’s initial draft of NAIC Valuation Manual Section II and VM-22 requirements associated with the ARCWG proposal. We ask for the VM-22 Subgroup’s consideration of the language herein as a foundation for further drafting efforts, in your efforts to advance toward an NAIC fixed annuity PBR framework.

Please let us know if you have any follow-up inquiries in response to this document. Again, we appreciate the opportunity to propose the fixed annuity framework and all of the efforts made by the VM-22 Subgroup to focus on this topic.

Sincerely,
Ben Slutsker
Chairperson, Annuity Reserves and Capital Work Group
American Academy of Actuaries

---

\(^1\) The American Academy of Actuaries is a 19,500-member professional association whose mission is to serve the public and the U.S. actuarial profession. For more than 50 years, the Academy has assisted public policymakers on all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues. The Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.
VM-22 PBR: Requirements for Principle-Based Reserves for Non-Variable Annuities

Drafting Overview: This document is the ARCWG-proposed draft Valuation Manual wording for VM-22 PBR for non-variable annuities. The edits reflected in this draft are made in association with the recommendations in the Annuity Reserves Work Group-proposed VM-22 presentation, exposed by the VM-22 Subgroup in October 2020. Each section shows editorial mark-ups compared to existing VM-20 or VM-21 wording, which is included as a draft note at the beginning of each section (with the only exceptions being Sections 1 and 2 that do not contain mark-ups to existing Valuation Manual wording).

Section 1: Background

Drafting Note: All revisions shown in this section are in comparison to Section 1 in VM-21.

A. Purpose

These requirements establish the minimum reserve valuation standard for non-variable annuity (VA) and certain other policies and contracts (“contracts”) as defined in the Section 2.A, and issued on or after 1/1/2024 operative date of the Valuation Manual as required by Model Act #820. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts encompassed in Section 2-A, the Commissioners Reserve Valuation Method (CRVM).

Guidance Note: CRVM requirements apply to some group pension contracts.

The contracts subject to these requirements may be aggregated with the contracts subject to Actuarial Guideline XLIII — CARVM for Variable Annuities (AG 43), published in Appendix C of the AP&P Manual, for purposes of performing and documenting the reserve calculations.

Guidance Note:

Effectively, through reference in AG 43, the reserve requirements in VM-21 also apply to those contracts issued prior to Jan. 1, 2017, that would not otherwise be encompassed by the scope of VM-21. Reserves for contracts subject to VM-21 or AG 43 may be computed as a single group. If a company chooses to aggregate business subject to AG 43 with business subject to VM-21 in calculating the reserve, then the provisions in VM-G apply to this aggregate principle-based valuation.

Guidance Note:

Relationship to RBC Requirements

These requirements anticipate that the projections described herein are used for the determination of RBC for all of the contracts falling within the scope of these requirements. These requirements and the RBC requirements for the topics covered within Sections 4.A through 4.E are identical. However, while the projections described in these requirements are performed on a basis that ignores federal income tax, a company may elect to conduct the projections for calculating the RBC requirements by including projected federal income tax in the cash flows and reducing the discount interest rates used to reflect the effect of federal income tax as described in the RBC requirements. A company that has elected to calculate RBC requirements in this manner may not switch back to using a calculation that ignores the effect of federal income tax without approval from the domiciliary commissioner.

B. Principles

The projection methodology used to calculate the stochastic reserve, as well as the approach used to develop the Alternative Methodology, is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves.
Guidance Note: The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

Principle 1: The objective of the approach used to determine the stochastic reserve is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

Principle 2: The calculation of the stochastic reserve is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cash-flow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

Guidance Note: Examples where full aggregation between contracts may not be possible include experience rated group contracts and the operation of reinsurance treaties.

Principle 3: The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the stochastic reserve at the required CTE level if it were possible to calculate results over the joint distribution of all future outcomes. In applying this concept to the actual calculation of the stochastic reserve, the company should be guided by evolving practice and expanding knowledge base in the measurement and management of risk.

Guidance Note: The intent of Principle 3 is to describe the conceptual framework for setting assumptions. Section 10 provides the requirements and guidance for setting contract holder behavior assumptions and includes alternatives to this framework if the company is unable to fully apply this principle.

Principle 4: While a stochastic cash-flow model attempts to include all real-world risks relevant to the objective of the stochastic cash-flow model and relationships among the risks, it will still contain limitations because it is only a model. The calculation of the stochastic reserve is based on the results derived from the application of the stochastic cash-flow model to scenarios, while the actual statutory reserve needs of the company arise from the risks to
which the company is (or will be) exposed in reality. Any disconnect between the model and reality should be reflected in setting prudent estimate assumptions to the extent not addressed by other means.

**Principle 5:** Neither a cash-flow scenario model nor a method based on factors calibrated to the results of a cash-flow scenario model can completely quantify a company’s exposure to risk. A model attempts to represent reality but will always remain an approximation thereto and, hence, uncertainty in future experience is an important consideration when determining the stochastic reserve. Therefore, the use of assumptions, methods, models, risk management strategies (e.g., hedging), derivative instruments, structured investments or any other risk transfer arrangements (such as reinsurance) that serve solely to reduce the calculated stochastic reserve without also reducing risk on scenarios similar to those used in the actual cash-flow modeling are inconsistent with these principles. The use of assumptions and risk management strategies should be appropriate to the business and not merely constructed to exploit “foreknowledge” of the components of the required methodology.

**C. Risks Reflected**

1. The risks reflected in the calculation of reserves under these requirements arise from actual or potential events or activities that are both:

   a. Directly related to the contracts falling under the scope of these requirements or their supporting assets; and

   b. Capable of materially affecting the reserve.

2. Categories and examples of risks reflected in the reserve calculations include, but are not necessarily limited to:

   a. Asset risks

      i. **Separate account fund performance.**

      ii. Credit risks (e.g., default or rating downgrades).

      iii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).

      iv. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).

      v. Performance of equities, real estate, and Schedule BA assets.

      vi. Call risk on callable assets.

      vii. **Separate account fund performance.**

      viii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).

      viii. Currency risk.
b. Liability risks
   i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.
   ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.
   iii. Utilization risk associated with guaranteed living benefits.
   iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.
   v. Annuitzation risks.
   vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).
   vii. Applicable expense risks, including fluctuation maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks
   i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.
   ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).
   iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:
   a. Those not reflected in the determination of RBC.
   b. Those reflected in the determination of RBC but arising from obligations of the company not directly related to the contracts falling under the scope of these requirements, or their supporting assets, as described above.
   a. Those not associated with the policies or contracts being valued, or their supporting assets.
   b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:
   a. Asset risks
i. Liquidity risks associated with a sudden and significant levels of withdrawals and surrenders “run on the bank.”

b. Liability risks

i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.

ii. Catastrophic events (e.g., epidemics or terrorist events).

iii. Major breakthroughs in life extension technology that have not yet fundamentally altered recently observed mortality experience.

iv. Significant future reserve increases as an unfavorable scenario is realized.

c. General business risks

i. Deterioration of reputation.

ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.

iii. Poor management performance.

iv. The expense risks associated with fluctuating amounts of new business.

v. Risks associated with future economic viability of the company.

vi. Moral hazards.

vii. Fraud and theft.

D. Specific Definitions for VM-22

Buffer Annuity
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.

Deferred Income Annuity (DIA)
An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin one year or later after (or from) the issue date if the contract holder survives to a predetermined future age.

Fixed Indexed Annuity (FIA)
An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, typically with guaranteed principal.
Flexible Premium Deferred Annuity (FPDA)
An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

Funding Agreement
A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

Guaranteed Investment Contract (GIC)
Insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

Index Credit Hedge Margin
A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

Index Credit
Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to policy values that is linked to an index or indices. Amounts credited to the policy resulting from a floor on an index account are included.

Index Crediting Strategy
The strategy defined in a contract to determine index credits for a contract. This refers to underlying index, index parameters, date, timing, and other elements of the crediting method.

Index Parameter
Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

Longevity Reinsurance
An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a
permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

Market Value Adjustment (MVA) Annuity
An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

Modified Guaranteed Annuity (MGA)
A type of market-value adjusted annuity contract where the underlying assets are held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values that are based upon a market-value adjustment formula if held for shorter periods.

Multiple Year Guaranteed Annuity (MYGA)
A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

Pension Risk Transfer (PRT) Annuity
An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

Registered Index-Linked Annuity (RILA)
An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.

Single Premium Immediate Annuity (SPIA)
An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within one year after (or from) the issue date.

Single Premium Deferred Annuity (SPDA)
An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest
rates applicable at the time of conversion to the payout phase. May also include cases where the
premium is accepted for a limited amount of time early in the contract life, such as only in the
first duration.

**Stable Value Contract**
A contract that provides limited investment guarantees, typically preserving principal while
crediting steady, positive returns and protecting against losses or declines in yield. Underlying
asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general
account, a separate account, or in a third-party trust. These contracts often support defined
contribution or defined benefit retirement plan liabilities.

**Structured Settlement Contract (SSC)**
A contract that provides periodic benefits and is purchased with a single premium amount
stemming from various types of claims pertaining to court settlements or out-of-court
settlements from tort actions arising from accidents, medical malpractice, and other causes.
Adverse mortality is typically expected for these contracts.

**Synthetic GIC**
Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other
financial instruments, with the main difference being that the assets are owned by the
policyholder or plan trust.

**Term Certain Payout Annuity**
A contract issued, which offers guaranteed periodic payments for a specified period of time,
not contingent upon mortality or morbidity of the annuitant.

**Two-Tiered Annuity**
A deferred annuity with two tiers of account values. One, with a higher accumulation interest
rate, is only available for annuitization or death. The other typically contains a lower
accumulation interest rate, and is only available upon surrender.

1. The term “cash surrender value” means, for the purposes of these requirements, the amount
available to the contract holder upon surrender of the contract. Generally, it is equal to the
account value less any applicable surrender charges, where the surrender charge reflects
the availability of any free partial surrender options. However, for contracts where all or a
portion of the amount available to the contract holder upon surrender is subject to a market
value adjustment, the cash surrender value shall reflect the market value adjustment
consistent with the required treatment of the underlying assets. That is, the cash surrender
value shall reflect any market value adjustments where the underlying assets are reported
at market value, but it shall not reflect any market value adjustments where the underlying
assets are reported at book value.

2. The term “clearly defined hedging strategy” (CDHS) is defined in VM-01. In order to be
designated as a CDHS, the strategy must meet the principles outlined in Section 1.B
(particularly Principle 5) and shall, at a minimum, identify:
   a. The specific risks being hedged (e.g., delta, rho, vega, etc.).
   b. The hedge objectives.
   c. The risks not being hedged (e.g., variation from expected mortality, withdrawal,
and other utilization or decrement rates assumed in the hedging strategy, etc.).

d.——The financial instruments that will be used to hedge the risks.

e.——The hedge trading rules, including the permitted tolerances from hedging objectives.

f.——The metric(s) for measuring hedging effectiveness.

g.——The criteria that will be used to measure hedging effectiveness.

h.——The frequency of measuring hedging effectiveness.

i.——The conditions under which hedging will not take place.

j.——The person or persons responsible for implementing the hedging strategy.

Guidance Note: It is important to note that strategies involving the offsetting of the risks associated with VA guarantees with other products outside of the scope of these requirements (e.g., equity-indexed annuities) do not currently qualify as a clearly defined hedging strategy under these requirements.

3.——The term “guaranteed minimum death benefit” (GMDB) means a provision (or provisions) for a guaranteed benefit payable on the death of a contract holder, annuitant, participant or insured where the amount payable is either (i) a minimum amount; or (ii) exceeds the minimum amount and is:

——is increased by an amount that may be either specified by or computed from other policy or contract values; and

——has the potential to produce a contractual total amount payable on such death that exceeds the account value, or

——in the case of an annuity providing income payments, guarantee payment upon such death of an amount payable on death in addition to the continuation of any guaranteed income payments.

Guidance Note: The definition of GMDB includes benefits that are based on a portion of the excess of the account value over the net of premiums paid less partial withdrawals made (e.g., an earnings enhanced death benefit).

4.——The term “total asset requirement” (TAR) means the sum of the reserve determined from the VM-21 requirements prior to any adjustment for the elective phase-in pursuant to Section 2.B plus the C3 RBC amount from LR027-step (paragraph D) prior to any adjustment for phase in or smoothing.
Section 2: Scope and Effective Date

Drafting Note: There are no revisions shown in this section compared to VM-21 or other chapters Valuation Manual, since the write-up is largely new for VM-22.

A. Scope

Subject to the requirements of this VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

- Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
- GICs
- Synthetic GICs
- Stable Value Contracts
- Funding Agreements

Products in scope of VM-22 include fixed annuities which consist of, but are not limited to, the following list:

- **Account Value Based Annuities**
  - Deferred Annuities (SPDA & FPDA)
  - Multi-Year Guarantee Annuities (MYGA)
  - Fixed Indexed Annuities (FIA)
  - Market-Value Adjustments (MVA)
  - Two-tiered Annuities
  - Guarantees/Benefits/Riders on Fixed Annuity Contracts

- **Payout Annuities**
  - Single Premium Immediate Annuities (SPIA)
  - Deferred Income Annuities (DIA)
  - Term Certain Payout Annuity
  - Pension Risk Transfer Annuities (PRT)
  - Structured Settlement Contracts (SSC)
  - Longevity Reinsurance

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.

B. Effective Date & Transition

**Effective Date**

These requirements apply for valuation dates on or after January 1, 2024.
Transition

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the first three years following the effective date of VM-22 PBR. If a company during the three years elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.
Section 3: Reserve Methodology

Drafting Note: All revisions shown in this section are in comparison to Section 3 in VM-21.

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve (following the requirements of Section 4) plus the additional standard projection amount (following the requirements of Section 6) less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C the Alternative Methodology (Section 7), plus the reserve for any contracts determined using the Alternative Methodology valued under applicable requirements in VM-A and VM-C (following the requirements of Section 7).

Guidance Note: Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves, per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

Where reinsurance is ceded for all or a portion of the contracts, all components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (such costs and benefits) in the reserve calculation.

C. To Be Determined The Additional Standard Projection Amount

The additional standard projection amount is determined by applying one of the two standard projection methods defined in Section 6. The same method must be used for all contracts within a group of contracts that are aggregated together to determine the reserve, and the additional standard projection amount excluding any contracts whose reserve is determined using the Alternative Methodology. The company shall elect which method they will use to determine the additional standard projection amount. The company may not change that election for a future valuation without the approval of the domiciliary commissioner.

D. The Stochastic Reserve

1. The stochastic reserve shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C Alternative Methodology, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.E. The stochastic reserve may be determined in aggregate for all contracts falling within the scope of these requirements—i.e., a single model segment—or, at the option of the company, it may be determined by subgrouping contracts into model segments.

2. The stochastic reserve amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve following the requirements of Section 4.
3. The reserve may be determined in aggregate across various groups of contracts as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles:

a. Aggregate in a manner that is consistent with the company’s risk management strategy and reflects the likelihood of any change in risk offsets that could arise from shifts between product types, and

b. Using prudent actuarial judgement, consider the following elements when aggregating groups of contracts: whether groups of contracts are part of the same portfolio (or different portfolios that interact), same integrated risk management system, administered/managed together

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.

5. To the extent that these limits on aggregation result in more than one model segment, the stochastic reserve shall equal the sum of the stochastic reserve amounts computed for each model segment and scenario reserve amounts computed for each model segment for which the company elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test Alternative Methodology

For a group of variable deferred annuity contracts that contain either no guaranteed benefits or only GMDBs—i.e., no VAGLBs—the reserve may be determined using the Alternative Methodology described in Section 7 rather than using the approach described in Section 3.C and Section 3.D. However, in the event that the approach described in Section 3.C and Section 3.D has been used in prior valuations for that group of contracts, the Alternative Methodology may not be used without approval from the domiciliary commissioner.

The reserve for the group of contracts to which the Alternative Methodology is applied shall not be less than the aggregate cash surrender value of those contracts.

1. To the extent that certain groups of contracts pass one of the defined stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology pursuant to applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for immediate annuities specified in Section 13.

   a. For dividend-paying contracts, a dividend liability shall be established upon following requirements in VM-A and VM-C, as described above, for the base contract.

   **Guidance Note:** The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018; AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on/after 2018; Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contracts when performing the exclusion tests should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserves in Section D above.
F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements using the method outlined in Section 12.

G. Prudent Estimate Assumptions:

1. With respect to the Stochastic Reserve in Section 3.C, the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

3. To determine the prudent estimate assumptions, the stochastic reserve shall also follow the requirements in Sections 4 and 9 for asset assumptions, Section 10 for policyholder behavior assumptions, and Section 11 for mortality assumptions.

G. Reserve to Be Held in the General Account

The portion of the aggregate reserve held in the general account shall not be less than the excess of the aggregate reserve over the aggregate cash surrender value held in the separate account and attributable to the separate account portion of all such contracts. For contracts for which a cash surrender value is not defined, the company shall substitute for cash surrender value held in the separate account the implicit amount for which the contract holder is entitled to receive income based on the performance of the separate account. For example, for a variable payout annuity for which a specific number of units is payable, the implicit amount could be the present value of that number of units, discounted at the assumed investment return and defined mortality, times the unit value as of the valuation date.

Guidance Note: This approach is equivalent to assuming that the separate account performance is equal to the assumed investment return.
Section 4: Determination of Stochastic Reserve

Drafting Note: All revisions shown in this section are in comparison to Section 4 in VM-21.

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Section 4.D. The company shall project cash flows including the following:

   a. Revenues received by the company including gross premiums received from the policyholder (including any due premiums as of the projected start date).

   b. All material benefits projected to be paid to policyholders—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.

   Guidance Note: Amounts charged to account values on general account business are not revenue; examples include rider charges and expense charges.

   c. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.J.

   d. Insurance company expenses (including overhead and investment expense), commissions, fund expenses, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses), and

   e. Net cash flows associated with any reinsurance.

   f. Cash flows from hedging instruments as described in Section 4.A.4. are to be reflected on a basis consistent with the requirements herein.

   g. Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

   h. If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.
Guidance Note: Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance). Cash flows from any fixed account options also shall be included. Any market value adjustment assessed on projected withdrawals or surrenders also shall be included (whether or not the cash surrender value reflects market value adjustments). Throughout the projection, all assumptions shall be determined based on the requirements herein. Accumulated deficiencies shall be determined at the end of each projection year as the sum of the accumulated deficiencies for all contracts within each model segment.

Guidance Note: Section 4.A.1 requires market value adjustments (MVAs) on liability cash flows to be reflected because in a cash flow model, assets are assumed to be liquidated at market value to cover the cash outflow of the cash surrender; therefore, inclusion of the market value adjustment aligns the asset and liability cash flows. This may differ from the treatment of MVAs in the definition of cash surrender value (Section 1.D), which defines the statutory reserve floor for which the values must be aligned with the annual statement value of the assets.

2. Grouping of Variable Funds and Subaccounts

Index Crediting Strategies

The portion of the starting asset amount held in the separate account represented by the variable funds and the corresponding account values. Index crediting strategies may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of the funds. Each index crediting strategy. In assigning each variable fund and the variable subaccounts index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the fund index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

An appropriate proxy fund for each variable subaccount shall be designed in order to develop the investment return paths. The development of the scenarios for the proxy funds is a fundamental step in the modeling and can have a significant impact on results. As such, the company must map each variable account to an appropriately crafted proxy fund normally expressed as a linear combination of recognized market indices, sub-indices or funds.
3. Model Cells

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.

4. Modeling of Hedges

a. For a company that does not have a CDHS future hedging program tied directly to the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

b) No hedge positions—in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.

Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company with a CDHS that has a future hedging program tied directly to the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders

b) Existing hedging instruments that are currently held by the company for this purpose in support of the contracts falling under the scope of these requirements shall be included in the starting assets. Existing hedging instruments that are currently held by the

© 2022 National Association of Insurance Commissioners
company for any other purpose should be modeled consistently with the requirements of Section 4.A.4.a.ii.

c) An Index Credit Hedge Margin for these instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible company experience and be no less than \([X\%]\) multiplicatively of the interest credited. In the absence of sufficient and credible company experience, a margin of \([Y\%]\) shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than \([Y\%]\). It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve.

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future through the execution of CDHS. Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve as the weighted average of two CTE values; first, a CTE70 (“best efforts”) representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE70 (“adjusted”) which shall use only hedge assets held by the company on the valuation date and no future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9. The stochastic reserve shall be the weighted average of the two CTE70 values, where the weights reflect the error factor (E) determined following the guidance of Section 9.C.4.

c) Consistent with Section 4.A.4.b.i., the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.i.c.)
d) The use of products not falling under the scope of these requirements (e.g., equity-indexed annuities) as a hedge shall not be recognized in the determination of accumulated deficiencies.

**Guidance Note:** Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other fixed income assets supporting the contracts, and a margin is reflected rather than modeling using a CTE70 adjusted run with no future hedge purchases. If a company has a more comprehensive hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or economic hedging), an appropriate and documented bifurcation method should be used in the application of sections 4.A.4.b.i and 4.A.4.b.ii above for the hedge modeling and justification. Such bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

**Guidance Note:** The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.

5. **Revenue Sharing**

If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each of the following requirements set forth in VM 21 Section 4.A.5 are met:

- The net revenue-sharing income is received by the company.
- The net revenue-sharing income is not already accounted for directly or indirectly as a company asset.

**Guidance Note:** For purposes of this section, net revenue-sharing income is considered to be received by the company if it is paid directly to the company through a contractual agreement with either the entity providing the net revenue-sharing income or an affiliated company that receives the net revenue-sharing income. Net revenue-sharing income also would be considered to be received if it is paid to a subsidiary that is owned by the company and if 100% of the statutory income from that subsidiary is reported as statutory income of the company. In this case, the company needs to assess the likelihood that future net revenue-sharing income is reduced due to the reported statutory income of the subsidiary being less than future net revenue-sharing income received.

Signed contractual agreement(s) are in place as of the valuation date and support the current payment of the net revenue-sharing income.

The net revenue-sharing income is not already accounted for directly or indirectly as a company asset.
The amount of net revenue-sharing income to be used shall reflect the company’s assessment of factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):

The terms and limitations of the agreement(s), including anticipated revenue, associated expenses and any contingent payments incurred or made by either the company or the entity providing the net revenue sharing as part of the agreement(s).

The relationship between the company and the entity providing the net revenue-sharing income that might affect the likelihood of payment and the level of expenses.

The benefits and risks to both the company and the entity paying the net revenue-sharing income of continuing the arrangement.

The likelihood that the company will collect the net revenue-sharing income during the term(s) of the agreement(s) and the likelihood of continuing to receive future revenue after the agreement(s) has ended.

The ability of the company to replace the services provided to it by the entity providing the net revenue-sharing income or to provide the services itself, along with the likelihood that the replaced or provided services will cost more to provide.

The ability of the entity providing the net revenue-sharing income to replace the services provided to it by the company or to provide the services itself, along with the likelihood that the replaced or provided services will cost more to provide.

The amount of projected net revenue-sharing income shall reflect a margin (which decreases the assumed net revenue-sharing income) directly related to the uncertainty of the revenue. The greater the uncertainty, the larger the margin. Such uncertainty is driven by many factors, including the potential for changes in the securities laws and regulations, mutual fund board responsibilities and actions, and industry trends. Since it is prudent to assume that uncertainty increases over time, a larger margin shall be applied as time that has elapsed in the projection increases.

All expenses required or assumed to be incurred by the company in conjunction with the arrangement providing the net revenue-sharing income, as well as any expenses assumed to be incurred by the company in conjunction with the assumed replacement of the services provided to it (as discussed in Section 4.A.5.b.v), shall be included in the projections as a company expense under the requirements of Section 4.A.1. In addition, expenses incurred by either the entity providing the net revenue-sharing income or an affiliate of the company shall be included in the applicable expenses discussed in Section 4.A.1 and Section 4.A.5.a that reduce the net revenue-sharing income.

The company is responsible for reviewing the revenue-sharing agreements and verifying compliance with these requirements.

The amount of net revenue-sharing income assumed in a given scenario shall not exceed the sum of (i) and (ii), where:
Is the contractually guaranteed net revenue-sharing income projected under the scenario; and

Is the company’s estimate of non-contractually guaranteed net revenue-sharing income before reflecting any margins for uncertainty multiplied by the following factors:

1.00 in the first projection year.
0.95 in the second projection year.
0.90 in the third projection year.
0.85 in the fourth projection year.
0.80 in the fifth and all subsequent projection years.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods.

7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. General For a given scenario, the scenario reserve is the sum of shall be determined using one of two methods described below:

   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   Guidance Note: The greatest present value of accumulated deficiencies can be negative.

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defeasement of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period starting asset amount. When using the direct iteration method, the scenario reserve will equal the final starting asset amount determined according to Section 4.B.4.

   The scenario reserve for any given scenario shall not be less than the cash surrender value in aggregate on the valuation date for the group of contracts modeled in the projection.

2. Discount Rates
In determining the scenario reserve, unless using the direct iteration method pursuant to Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

a. The additional invested asset portfolio for a scenario is a portfolio of general account assets as of the valuation date, outside of the starting asset portfolio, that is required in that projection scenario so that the projection would not have a positive accumulated deficiency at the end of any projection year. This portfolio may include only (i) General Account assets available to the company on the valuation date that do not constitute part of the starting asset portfolio; and (ii) cash assets.

Guidance Note:

Additional invested assets should be selected in a manner such that if the starting asset portfolio were revised to include the additional invested assets, the projection would not be expected to experience any positive accumulated deficiencies at the end of any projection year.

It is assumed that the accumulated deficiencies for this scenario projection are known.

b. To determine the NAER on additional invested assets for a given scenario:

   i. Project the additional invested asset portfolio as of the valuation date to the end of the projection period,
      
      a) Investing any cash in the portfolio and reinvesting all investment proceeds using the company’s investment policy.
      
      b) Excluding any liability cash flows.
      
      c) Incorporating the appropriate returns, defaults and investment expenses for the given scenario.

   ii. If the value of the projected additional invested asset portfolio does not equal or exceed the accumulated deficiencies at the end of each projection year for the scenario, increase the size of the initial additional invested asset portfolio as of the valuation date, and repeat the preceding step.

   iii. Determine a vector of annual earned rates that replicates the growth in the additional invested asset portfolio from the valuation date to the end of the projection period for the scenario. This vector will be the NAER for the given scenario.

   iii-iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.c, as a safe harbor.
4. Direct Iteration In lieu of the method described in Section 4.B.2 and Section 4.B.3 above, the company may solve for the amount of starting assets which, when projected along with all contract cash flows, result in the defeasement of all projected future benefits and expenses at the end of the projection horizon with no accumulated deficiencies at the end of any projection year during the projection period.

C. Projection Scenarios

1. Number of Scenarios

The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

Treasury Department interest rate curves, as well as investment return paths for general account equity index funds, equities, and fixed income assets and separate account fund performance shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.

D. Projection of Assets

1. Starting Asset Amount

a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:

i. All of the separate account assets supporting the contracts;

ii. Any hedge instruments held in support of the contracts being valued; and

iii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i) and (ii).

Guidance Note: Deferred hedge gains/losses developed under SSAP No. 108—Derivatives Hedging Variable Annuity Guarantees are not included in the starting assets.
b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

To the extent that the sum of the value of hedge assets, or cash, or other general account assets in an amount equal to the aggregate market value of such hedge assets, and the value of separate account assets supporting the contracts is greater than the approximate value of statutory reserves as of the start of the projections, then the company shall include enough negative general account assets or cash such that the starting asset amount equals the approximate value of statutory reserves as of the start of the projections.

2. Valuation of Projected Assets

For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

Guidance Note: Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. Separate Account Assets

For purposes of determining the starting asset amounts in Section 4.D.1 and the valuation of projected assets in Section 4.D.2, assets held in a separate account shall be summarized into asset categories determined by the company as discussed in Section 4.A.2.

4. General Account Assets

a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:

i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;

ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall
appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the model investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the model investment strategy and any non-prescribed asset spreads shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained by substituting an alternative investment strategy in which all fixed income reinvestment assets are public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 150% PBR credit rating 3 (Aa2/AA)

iii. 40% 6 (A2/A) and 50% PBR credit rating 63 (Aa2/AA)

vi.iv. 40% PBR credit rating 9 (Baa/BBB)

Policy loans, equities and derivative instruments associated with the execution of a clearly defined hedging strategy are not affected by this requirement.

Drafting Note: This limitation is being referred to Life Actuarial (A) Task Force for review.

b.c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.iii and Section 4.D.4.a.iv, recognizing that initial assets that mature...
during the projection may have different characteristics than modeled reinvestment assets.

**Guidance Note:** This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

5.4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F.

b. Cash flows from general account index funds and equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for separate account assets, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.
iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.

c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.I.

E. Projection of Annuitzation Benefits (Including GMIBs and GMWBs)

1. Assumed Annuitzation Purchase Rates at Election

a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such payout rates shall reflect the payout rate specified in the contract.

a-b. For purposes of projecting future elective annuitzation benefits (including annuitzations stemming from the election of a GMIB) and withdrawal amounts from GMWBs, the projected annuitzation purchase rates shall be determined assuming that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuitzation Options

a. For contracts projected to elect future annuitzation options (including annuitzations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections may assume one of the following at the company's option:

The contract is treated as if surrendered at an amount equal to the statutory reserve that would be required at such time for a fixed payout annuity benefit equivalent to the guaranteed benefit amount (e.g., GMIB or GMWB benefit payments)

The contract is assumed to will stay in force, and the projected periodic payments are paid, and the associated maintenance expenses are incurred.

b. Where mortality improvement is used to project future annuitzation purchase rates, as discussed in Section 4.E.1 above, mortality improvement also shall be reflected on a consistent basis in either the determination of the reserve in Section 4.E.2.a.i above or the projection of the periodic payments in Section 4.E.2.a.ii.

3. Projected Statutory Reserve for Payout Annuity Benefits

If the statutory reserve for payout annuity benefits referenced above in Section 4.E.2.a requires a parameter that is not determined in a formulaic fashion, the company must make a reasonable and supportable assumption regarding this parameter.
F. Frequency of Projection and Time Horizon

1. Use of an annual cash-flow frequency ("timestep") is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

2. Care must be taken in simulating fee income and expenses when using an annual time step. For example, recognizing fee income at the end of each period after market movements, but prior to persistency decrements, would normally be an inappropriate assumption. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

Guidance Note: As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs

When determining a stochastic reserve, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

Drafting Note: All revisions shown in this section are in comparison to Section 5 in VM-21.

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the additional standard projection amount, the stochastic reserve determined using projections, and/or the reserve amount valued using requirements in VM-A and VM-C determined using the Alternative Methodology, as applicable—on both bases. Sections 5.A.2 and through 5.A.34 discuss adjustments to inputs necessary to determine these components on both a post-reinsurance ceded and a pre-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all anticipated projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions both premiums and recoveries are determined by recognizing any limitations in the reinsurance treaties, such as caps on recoveries or floors on premiums.

i. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

ii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

iii. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the aggregate reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum reserve by the absolute value of such reductions in surplus.
b. In order to determine the stochastic reserve on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

i. For a standard coinsurance treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection based on using the same starting assets on the ceded portion of the policies that are similar to those supporting the retained portion of the ceded policies or supporting similar types of policies. Scaling up each asset supporting the retained portion of the contract is also an acceptable methodology as for the aggregate reserve post-reinsurance ceded and by ignoring, where appropriate, all anticipated reinsurance premiums or other costs and all reinsurance recoveries in the projections.

Guidance Note: For standard pro rata insurance treaties (does not include experience refunds), where allocated expenses are similar to the renewal expense allowance, reflecting the quota share applied to the present value of future reinsurance cash flows pertaining to the reinsured block of business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the ceded liabilities. This could be the case for several forms of reinsurance: funds withheld coinsurance; modified coinsurance; coinsurance with a trust. To the extent these assets would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard coinsurance treaty. To the extent these assets exceeded what might be needed to defease the ceded liabilities (perhaps an over collateralization requirement in a trust), the inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, Principle-Based Reserves for Life Products under the NAIC Valuation Manual, provides possible methods for constructing a hypothetical pre-reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies that reflect the assuming company’s experience for the business segment to which the reinsured policies belong and reflect the terms of the reinsurance agreement.

3. Reserve Determined Upon Passing the Exclusion Test using the Alternative Methodology

If a company chooses to use the Alternative Methodology stochastic exclusion test and elects to use a methodology pursuant to applicable Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology produces reserves on a pre-reinsurance ceded basis. Therefore, where reinsurance is ceded, the Alternative Methodology reserve must be modified to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties in the determination of the aggregate reserve post-reinsurance ceded adjusted for any reinsurance ceded accordingly. In addition, the reserves valued under applicable Sections in VM-A and VM-C Alternative Methodology, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance and post-reinsurance reserves may result in different outcomes for the exclusion test. In particular, it is possible that the pre-reinsurance reserves would pass the relevant exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance reserves might not.
4. To Be Determined: Additional Standard Projection Amount

Where reinsurance is ceded, the additional standard projection amount shall be calculated as described in Section 6 to reflect the reinsurance costs and reinsurance recoveries under the reinsurance treaties. The additional standard projection amount shall also be calculated pre-reinsurance ceded using the methods described in Section 6 but ignoring the effects of the reinsurance ceded.
Section 6: To Be Determined
Section 7: Exclusion Testing

Drafting Note: All revisions shown in this section are in comparison to Section 6 in VM-20.

A. Stochastic Exclusion Test Requirement Overview

1. Requirements to pass the Stochastic Exclusion Test:

   1. The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation if the stochastic exclusion test (SET) is satisfied for that group of contracts. The company has the option to calculate or not calculate the SET.

      a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

      b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups of contracts. If the reserve methodology described in Section 4 is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.

      c. A company may not exclude a group of contracts from the stochastic reserve requirements if there are one or more future hedging programs associated with the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9.A.1.

B. Types of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

1. Stochastic Exclusion Ratio Test (SERT) — Annually and within 12 months before the valuation date the company demonstrates that the groups of contracts pass the SET defined in Section 7.C.6.A.2.

2. Stochastic Exclusion Demonstration Test — In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.6.A.3.

3. SET Certification Method — For groups of contracts other than variable life contracts, future hedging programs, or ULSG pension risk transfer business, in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts is not subject to material aggregate risk levels across interest rate risk, longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

Guidance Note: The qualified actuary should develop documentation to support the actuarial certification that presents his or her analysis clearly and in detail sufficient for another actuary to comprehend.
understand the analysis and reasons for the actuary’s conclusion that the group of policies contracts is not subject to material interest rate risk, longevity risk, or asset return volatility risk. Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:

a) **A demonstration that NPRs using requirements under VM-A and VM-C for the group of policies contracts calculated according to Section 3 are at least as great as the assets required to support the group of policies contracts using the company’s cash-flow testing model under each of the 16 scenarios identified in Section 6 or alternatively each of the New York seven scenarios.**

b) A demonstration that the group of policies contracts passed the SERT within 36 months prior to the valuation date and the company has not had a material change in its interest rate risk.

c) A qualitative risk assessment of the group of policies contracts that concludes that the group of policies contracts does not have material interest rate risk or asset return volatility. Such assessment would include an analysis of product guarantees, the company’s non-guaranteed elements (NGEs) policy, assets backing the group of policies contracts and the company’s investment strategy.

C. **Stochastic Exclusion Ratio Test**

1. In order to exclude a group of policies contracts from the stochastic reserve requirements using the method allowed under Section 6.A.1.a, the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of \((b - a)/ca\) is less than \(6\%\) where:

   a. \(a\) = the adjusted deterministic scenario reserve described in Section 6.A.2.b.i Paragraph C.2.a.i below using economic scenario 9, the baseline economic scenario, as described in Appendix 1.E of VM-20.

   b. \(b\) = the largest adjusted scenario reserve described in Section 6.A.2.b.i Paragraph C.2.b below under any of the other 15 economic scenarios described in Appendix 1.E of VM-20 under both \([95\%]\) and \([105\%]\) of anticipated experience mortality excluding margins.

   iii. \(c\) = an amount calculated from the baseline economic scenario described in Appendix 1.E that represents the present value of benefits for the policies, adjusted for reinsurance by subtracting ceded benefits. For clarity, premium, ceded premium, expense, reinsurance expense allowance, modified coinsurance reserve adjustment and reinsurance experience refund cash flows shall not be considered “benefits,” but items such as death benefits, surrender or withdrawal benefits and policyholder dividends shall be. For this purpose, the company shall use the benefits cash flows from the calculation of quantity “a” and calculate the present value of those cash flows using the same path of discount rates as used for “a.”

**Guidance Note:** Note that the numerator should be the largest adjusted DR scenario reserve for scenarios other than the baseline economic scenario, minus the adjusted DR scenario reserve for
the baseline economic scenario. This is not necessarily the same as the biggest difference from the adjusted DR scenario reserve for the baseline economic scenario, or the absolute value of the biggest difference from the adjusted DR scenario reserve for the baseline economic scenario, both of which could lead to an incorrect test result.

2. In calculating the ratio in Section 6.A.2.a subsection (1) above:

a. The company shall calculate an adjusted deterministic scenario reserve for the group of contracts for each of the 16 scenarios that is equal to either (ai) or (bii) below:

i. The deterministic scenario reserve defined in Section 4.A, but with the following differences:
   a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph C.1.b of this section.
   b) Using the interest rates and equity return assumptions specific to each scenario.
   c) Using NAER and discount rates defined in Section 7.H.4 specific to each scenario to discount the cash flows.
   d) Shall reflect future mortality improvement in line with anticipated experience assumptions.
   e) Shall not reflect correlation between longevity and economic risks.

ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:
   a) Using the interest rates and equity return assumptions specific to each scenario.
   b) Using the mortality scalars described in Paragraph C.1.b of this section.
   c) Using the methodology to determine NAER and discount rates defined in Section 7.H.4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current available baseline economic scenario and the 15 other 16 economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.
e. Mortality improvement beyond the projection start date may not be reflected in the mortality assumption for the purpose of calculating the stochastic exclusion ratio.

e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the exclusion test under a pre-reinsurance-ceeded basis upon determining the pre-reinsurance reserve-ceeded aggregate reserve.

3. If the ratio calculated in Section 6.A.2.a above this section is less than \( \delta \% \times \% \) pre-YRTnon-proportional reinsurance, but is greater than \( \delta \% \times \% \) post-YRTnon-proportional reinsurance, the group of contracts/policies will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted deterministic scenario reserve to economic scenarios is comparable pre- and post-YRTnon-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation • SERT = the ratio \((b-a)/a\) defined in Section 7.C.1(a) above

a) The pre-YRTnon-proportional reinsurance results are “gross of YRTnon-proportional,” with a subscript “gn,” so denoted SERTgn

b) The post-YRTnon-proportional results are “net of YRTnon-proportional,” with subscript “nn,” so denoted SERTnn

ii. If a block of business being tested is subject to one or more YRTnon-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of YRTnon-proportional” to mean net of all non-YRTprorata reinsurance but ignoring the YRTnon-proportional contract(s), and “net of YRTnon-proportional” to mean net of all reinsurance contracts. That is, treat YRTnon-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.

iii. So, if \( SERT_{gn} \times LPIR_{gn} \times LPIR_{nn} < 0.060 \) but \( SERT_{nn} \times LPIR_{nn} \times LPIR_{nn} > [x] \), then compute the largest percent increase in reserve (LPIR) = \((b-a)/a\), both “gross of YRTnon-proportional” and “net of YRTnon-proportional.”

\[
\begin{align*}
LPIR_{gn} \times LPIR_{nn} & = (b_{gn} - a_{gn})/a_{gn}d_{gn} \\
LPIR_{nn} \times LPIR_{nn} & = (b_{nn} - a_{nn})/a_{nn}d_{nn}
\end{align*}
\]

Note that the scenario underlying \( b_{gn} \times b_{nn} \) could be different from the scenario underlying \( b_{gn} \times b_{nn} \).

If \( SERT_{gn} \times LPIR_{gn} \times LPIR_{nn} < 0.060 \), \( SERT_{nn} \times LPIR_{nn} \times LPIR_{nn} < [x] \), then the block of contracts/policies passes the SERT.
b. Another more qualitative approach is to calculate the adjusted deterministic scenario reserves for the 16 scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.

4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method of Section 6.A.3.b.i or Section 6.A.3.b.ii in this section and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method of Section 6.A.1.a.iii in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve requirements using the methodology using the method as allowed under Section 6.A.1.a.ii above in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

a. The demonstration shall provide a reasonable assurance that if the stochastic reserve was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve exclusion, the resulting stochastic minimum reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve requirements.

b. If, as of the end of any calendar year, the company determines the minimum aggregate reserve for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.

c. The demonstration may be based on analysis from a date that precedes the valuation date for the initial year to which it applies if the demonstration includes an explanation of why the use of such a date will not produce a material change in the outcome, as compared to results based on an analysis as of the valuation date.

d. The demonstration shall provide an effective evaluation of the residual risk exposure remaining after risk mitigation techniques, such as derivative programs and reinsurance.

2. The company may use one of the following or another method acceptable to the insurance commissioner to demonstrate compliance with Section 6.A.3 asubsection 7.D.1 above:

a. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C [greater of [the quantity A and the quantity B]] is greater than the stochastic reserve calculated on a stand-alone basis, where:
A = the deterministic reserve, and  
B = the NPR less any associated due and deferred premium asset.

bii. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C greater of [the quantity A and the quantity B] is greater than the scenario reserve that results from each of a sufficient number of adverse deterministic scenarios, where:

A = the deterministic reserve, and  
B = the NPR less any associated due and deferred premium asset.

c. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-C greater of [the quantity A and the quantity B] is greater than the stochastic reserve calculated on a stand-alone basis, but using a representative sample of contracts/policies in the stochastic reserve calculations, where:

A = the deterministic reserve, and  
B = the NPR less any associated due and deferred premium asset.

d. Demonstrate that any risk characteristics that would otherwise cause the stochastic reserve calculated on a stand-alone basis to exceed greater of the deterministic reserve and the NPR, less any associated due and deferred premium asset the statutory reserve calculated in accordance with VM-A and VM-C, are not present or have been substantially eliminated through actions such as hedging, investment strategy, reinsurance or passing the risk on to the policyholder by contract provision.

E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve for a group of contracts using a single deterministic economic scenario, subject to the following conditions.

   a. The company certifies that economic conditions do not materially influence anticipated contract holder behavior for the group of policies. Examples of contract holder options that are materially influenced by economic conditions include surrender benefits, recurring premium payments, and guaranteed living benefits.

   b. The company certifies that the group of policies is not supported by a reinvestment strategy that contains future hedge purchases.

   c. The company must perform and disclose results from the stochastic exclusion ratio test following the requirements in Section 7.C, thereby disclosing the scenario reserve volatility across various economic scenarios.

   d. The company must disclose a description of contracts and associated features in the certification.
Drafting Note: Consider revisiting Paragraph E.1.c to possibly either require i) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario; or ii) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve for the group of contracts under the Deterministic Certification Option is determined as follows:
   
a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).
   
b. The stochastic reserve equals the scenario reserve following the requirements for Section 4.

Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Hedging Strategy

Drafting Note: All revisions shown in this section are in comparison to Section 9 in VM-21.

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company (a) only hedges index credits, or (b) clearly separates index credit hedging from other hedging. In those situations, the modeling of hedges supporting index credits can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.4.b.i.

21. Subject to Section 9.C.2, the appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the calculation of the stochastic reserve, determined in accordance with Section 3.D and Section 4.D.

32. If the company is following a CDHS, in accordance with an investment policy adopted by the board of directors, or a committee of board members, the company shall take into account the costs and benefits of hedge positions expected to be held by the company in the future along each scenario based on the execution of the hedging strategy, and it is eligible to reduce the amount of the stochastic reserve using projections otherwise calculated. The investment policy must clearly articulate the company’s hedging objectives, including the metrics that drive rebalancing/trading. This specification could include maximum tolerable values for investment losses, earnings, volatility, exposure, etc. in either absolute or relative terms over one or more investment horizons vis-à-vis the chance of occurrence. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than 6 months, including the hedging strategy, used to implement the investment policy.

43. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. This also is referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which also is referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

54. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio. Before either a new or revised hedging strategy can be used to reduce the amount of the stochastic reserve otherwise calculated, the hedging strategy should be in place (i.e., effectively implemented by the company) for at least three months. The company may meet the time requirement by having evaluated
the effective implementation of the hedging strategy for at least three months without actually having executed the trades indicated by the hedging strategy (e.g., mock testing or by having effectively implemented the strategy with similar annuity products for at least three months).

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.

3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserve otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserve needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserve attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock tested.

**Guidance Note:** No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta. Another example is that financial indices underlying typical hedging instruments typically do not perform exactly like the separate account funds, and hence the use of hedging instruments has the potential for introducing basis risk.

5. A safe harbor approach is permitted for CDHS reflection for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.
C. Calculation of Stochastic Reserve (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the CDHS modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to execute the CDHS model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no CDHS hedging strategy except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.i.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserve is given by:

\[
\text{Stochastic reserve} = \text{CTE70 (best efforts)} + E \times \max[0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}]
\]

4. The company shall specify a value for \(E\) (the “error factor”) in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of \(E\). The value of \(E\) may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, \(E\) must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recent 12 months, to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for \(E\).

6. Such a back-test shall involve one of the following analyses:

a. For companies that model hedge cash flows directly (“explicit method”), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses—both realized and unrealized—observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g. reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.
To support the choice of a low value of E, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of E by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an “implicit method” or “cost of reinsurance method”), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

i. Determine the hedge asset gains and losses—both realized and unrealized—incurred over the month attributable to equity, interest rate, and implied volatility movements.

ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).

iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.

iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the back-testing period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with no history, E should be at least 0.50.
However, E may be lower than 0.50 if some reliable experience is available and/or if the change in strategy is a refinement rather than a substantial change in strategy.

Guidance Note: The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or CDHS modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

E. Additional Considerations for CTE70 (best efforts)

If the company is following a CDHS, the fair value of the portfolio of contracts falling within the scope of these requirements shall be computed and compared to the CTE70 (best efforts) and CTE70 (adjusted). If the CTE70 (best efforts) is below both the fair value and CTE70 (adjusted), the company should be prepared to explain why that result is reasonable.

For the purposes of this analysis, the stochastic reserve and fair value calculations shall be done without requiring the scenario reserve for any given scenario to be equal to or in excess of the cash surrender value in aggregate for the group of contracts modeled in the projection.

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for purposes of reducing the stochastic reserve, the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or adverse estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the variable-fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited
to, a hedging strategy where material hedging assets will be obtained when the *variable fixed indexed* annuity account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the *variable fixed indexed* annuities and other in-scope products and these same sensitivities associated with the hedging assets. There may be scenarios that are particularly costly to discontinuous hedging strategies, especially where those result in large discontinuous changes in sensitivities (Greeks) associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve otherwise calculated.

6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

Drafting Note: All revisions shown in this section are in comparison to Section 10 in VM-21.

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the results. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, fund-index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to
the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.

2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more behaviors.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.

2. Using data from prior periods.
D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
   a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).
   b. Surrenders.
   c. Partial withdrawals (systematic and elective).
   d. Fund Account transfers (switching/exchanges).
   e. Resets/ratchets of the guaranteed amounts (automatic and elective).
   f. Future deposits.
   g. Income start date
   h. Commutation of benefit (from periodic payment to lump sum)

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions. For example:
   a. The impact of fund account transfers (intra-contract fund index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing, dollar cost averaging accounts, etc.) or if the contract provisions incentivize the contract holders to transfer between accounts.
   b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).
   c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

   Guidance Note: For some non-elective benefits (nursing home benefits for example), unless relevant company experience exists to the contrary, the use of incidence rates greater than zero after the surrender charge has ended, or the cash value was depleted might be inappropriate may not be prudent since it would reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.
4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):
   a. Gender.
   b. Attained age.
   c. Issue age.
   d. Contract duration.
   e. Time to maturity.
   f. Tax status.
   g. Fund Account value.
   h. Interest credited (current and guaranteed).
   i. Investment option Available indices.
   j. Guaranteed benefit amounts.
   k. Surrender charges, transaction transfer fees or other contract charges.
   l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100%
efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., the non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holder.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practicality, the use of dynamic models is encouraged, but not mandatory. Risk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers) may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of behavior consistent with the economic scenarios and other variables in the model, including the non-scenario tested assumptions. The company shall test the sensitivity of results to understand the materiality of making alternate assumptions and follow the guidance discussed above on setting assumptions for sensitive behaviors.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution). To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the model) in order to determine exactly which scenario results are included in the CTE measure. Rather, in light of the products being valued, the company should be mindful of the general characteristics of those scenarios likely to represent the tail of the loss distribution and consequently use prudent estimate assumptions for behavior that are reasonable and appropriate in such scenarios. For variable fixed annuities, these “valuation” scenarios would typically display one or more of the following attributes:

   a. Declining and/or volatile separate account asset index values, where applicable.
   b. Market index volatility, price gaps and/or liquidity constraints.
   c. Rapidly changing interest rates or persistently low interest rates.
   d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions:

   a. Remain logically and internally consistent across the scenarios tested.
b. Represent plausible outcomes.

c. Lead to appropriate, but not excessive, asset requirements.

4. The company should remember that the continuum of “plausibility” should not be confined
 or constrained to the outcomes and events exhibited by historic experience.

5. Companies should attempt to track experience for all assumptions that materially affect
 their risk profiles by collecting and maintaining the data required to conduct credible and
 meaningful studies of contract holder behavior.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed
 Living Benefits

Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse
 assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such
 experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living
 benefit may have relevance to the early durations of contracts with living benefits) and relevant to
 the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows
 for each projection interval for policy loan assets by modeling existing loan balances either
 explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject
 to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must
demonstrate that such substitution:

   a. Produces reserves that are no less than those that would be produced by modeling
      existing loan balances explicitly.

   b. Complies with the contract holder behavior requirements stated in
      Section 10 above in this section.

2. If the company models policy loans explicitly, the company shall:

   a. Treat policy loan activity as an aspect of contract holder behavior and subject to
      the requirements above in this section.

   b. Assign loan balances either to exactly match each policy’s utilization or to reflect
      average utilization over a model segment or sub-segments.

   c. Model policy loan interest in a manner consistent with policy provisions and with
      the scenario. Include interest paid in cash as a positive policy loan cash flow in that
      projection interval, but do not include interest added to the loan balance as a policy
      loan cash flow. (The increased balance will require increased repayment cash
      flows in future projection intervals.)

   d. Model policy loan principal repayments, including those that occur automatically
      upon death or surrender. Include policy loan principal repayments as a positive
      policy loan cash flow, per Section 4.A.1.h.
e. **Model additional policy loan principal.** Include additional policy loan principal as a negative policy loan cash flow, per Section 4.A.1.h (but do not include interest added to the loan balance as a negative policy loan cash flow).

f. Model any investment expenses allocated to policy loans and include them either with policy loan cash flows or insurance expense cash flows.

I. **Non-Guaranteed Elements**

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy costs or values and not guaranteed or not determined at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.

Examples of NGEs specific to fixed annuities include but are not limited to the following: fixed credited rates, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollup rates, rollup period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.J.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of an NGE that:
   a. Is not based on some aspect of the policy’s or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

   However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.
6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.

   a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve.

   b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

Drafting Note: All revisions shown in this section are in comparison to Section 11 in VM-21.

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining either the stochastic reserve or the reserve for any contracts determined using the Alternative Methodology. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.)

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between whether the payout annuities or deferred annuity contracts contain VAGLBs, and where the no-VAGLB segments would include both deferred annuity contracts with no guaranteed benefits or contracts with only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from...
similar industries or geographies that may be used to sub-divide inforce blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to how payout annuities vs. deferred annuities are distinguished.

Guidance Note: Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.

4. Margin for Data Uncertainty

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a plus (minus) segment to a minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require recategorization depending on whether it is gross or net of reinsurance.

B. Determination of Expected Mortality Curves

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2. for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.
3. No Data Requirements

i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:

\[ q_{x}^{20XX+n} = q_{x}^{20XX}(1 - G2_{x})^{n} \]

a. [2021 SOA Deferred Annuity Mortality Table] with [Projection Scale G2] for individual deferred annuities that do not contain guaranteed living benefits

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

\[ q_{x}^{2012+n} = q_{x}^{2012}(1 - G2_{x})^{n} \]

a. [The appropriate percentage (Fx) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual payout annuity contracts and deferred annuity contracts with guaranteed living benefits

b. [1983 Table “a”) for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_{x}^{1994+n} = q_{x}^{1994}(1 - AA_{x})^{n} \]

- the appropriate percentage (Fx) from Table 1 of the 2012 IAM Basic Table with Projection Scale G2 for contracts with no VAGLBs and expected deaths no greater than the appropriate percentage (Fx) from Table 1 of the 2012 IAM Basic Mortality Table with Projection Scale G2 for contracts with VAGLBs. If mortality experience on the business segment is expected to be atypical (e.g., demographics of target markets are known to have higher [lower] mortality than typical), these “no data” mortality requirements may not be adequate.

### iii. For a business segment with non-U.S. insureds, an established industry or national mortality table may be used, with approval from the domiciliary commissioner.

### 4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

#### a. Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.
b. Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by contract duration for an appropriate select period. As an alternative, if the company determines that mortality is affected by selection, the company could apply margins to the expected mortality in such a way that the actual mortality modeled does not depend on contract duration.

c. Modification and Relevance of Data

Even for a large company, the quantity of life exposures and deaths are such that a significant amount of smoothing may be required to determine expected mortality curves from mortality experience. Expected mortality curves, when applied to the recent historic exposures (e.g., three to seven years), should not result in an estimate of aggregate number of deaths less (greater) than the actual number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying data), older data may no longer be relevant. The “age” of the experience data used to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors that include, but are not limited to, trends in mortality experience, trends in exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative to mortality by amounts, changes in the mix of business and product features that could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves with the mortality assumption described in Section 11.B.3.a mortality table consistent with a statutory valuation mortality table. For contracts with no VAGLBs, the table shall be consistent with the appropriate percentage ($F_x$) from Table 1 of the 2012 IAM Basic Table with Projection Scale G2; and for contracts with VAGLBs, the table shall be consistent with the appropriate percentage ($F_x$) from Table 1 of the 2012 IAM Basic Mortality Table with Projection Scale G2. The approach used to adjust the curves shall suitably account for credibility.

**Guidance Note:** For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the statutory valuation mortality table used in the blending.

2. Adjustment of Statutory Valuation Mortality for Improvement
For purposes of the adjustment for credibility, the statutory valuation mortality table for a plus segment may be and the statutory valuation mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective statutory valuation mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves (discussed in Section 11.B).

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.

b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.

f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve. If such an adjustment would reduce the stochastic reserve, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Allocation of Aggregate Reserves to the Contract Level

Drafting Note: All revisions shown in this section are in comparison to Section 11 in VM-21.

Section 23.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

For contracts valued under the alternative methodology, the alternative methodology calculations provide a contract level calculation that may be a reasonable basis for allocation.

1. As an example, consider a company with the results of the following three contracts:

Table 12.1: Sample Allocation of Aggregate Reserve

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td></td>
<td>140</td>
</tr>
</tbody>
</table>
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>37.09</td>
<td>50.91</td>
<td>52.00</td>
<td>140.00</td>
<td></td>
</tr>
</tbody>
</table>

Option 2: Actuarial Present Value Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve defined in Section 3.D.
   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.
   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve defined in 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:
### Table 12.1: Hypothetical Sample Allocation of Aggregate Reserve

</tr>
</tbody>
</table>

*Cash Surrender Value  
**Guaranteed Lifetime Withdrawal Benefit

**Guidance Note:** The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.

3. shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts. The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis. For contracts valued under the alternative methodology, the alternative methodology calculations provide a contract level calculation that may be a reasonable basis for allocation.

4. As an example, consider a company with the results of the following three contracts:

<table>
<thead>
<tr>
<th>Contract</th>

Section 13: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

Drafting Note: All revisions shown in this section are in comparison to the current VM-22 requirements.

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section by VM-22:
   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

Guidance Note: For Section 13.A.2.d, Section 13.A.2.e, Section 13.A.2.f, Section 13.A.2.h and Section 13.A.2.i above, there is no restriction on the type of contract that may give rise to the benefit.

3. Exemptions:
   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section
13.A.2.d1.B.4, Section 13.A.2.e1.B.5, Section 13.A.2.f1.B.6, Section 13.A.2.g1.B.7 or Section 13.A.2.h1.B.8, the company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 13 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B) (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C) (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:

   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or

   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or

   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 13.B.1.c2.A.3 above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.
3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.

4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 13 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*

   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.
b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:

**Table 3-1: Assignment to Valuation Rate Bucket by Reference Period Only**

<table>
<thead>
<tr>
<th>RP ≤ 5 Years</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
</tbody>
</table>

c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

**Table 3-2: Assignment to Valuation Rate Bucket by Reference Period and Initial Age**

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5Y</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>90+</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>80–89</td>
<td>B</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>70–79</td>
<td>C</td>
<td>C</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>&lt; 70</td>
<td>D</td>
<td>D</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

2. Premium Determination Dates

a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

**Table 3-3: Premium Determination Dates**

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d and A.2.e</td>
<td>Fixed payout annuities resulting from settlement options or annuitizations from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
</tbody>
</table>
b. Immaterial Change in Consideration

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

3. Statutory Maximum Valuation Interest Rate

a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 13.C.1.A) and its Premium Determination Date (Section 13.C.2.B) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.

b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.

c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.

d. Quarterly Valuation Rate:

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ I_q = R + S - D - E \]

Where:

<table>
<thead>
<tr>
<th>A.2.g</th>
<th>Fixed income payment streams from CDAs, AV becomes 0</th>
<th>Date on which AV becomes 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
<tr>
<td>A.2.i</td>
<td>Group annuity and related certificates</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
</tbody>
</table>
a.  R is the reference rate for that Valuation Rate Bucket (defined in Section 13.C.4D);

b.  S is the spread rate for that Valuation Rate Bucket (defined in Section 13.C.5E);

c.  D is the default cost rate for that Valuation Rate Bucket (defined in Section 13.C.6F);

and

d.  E is the spread deduction defined as 0.25%.

e.  Daily Valuation Rate:

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[ I_d = I_q + C_{d-1} - C_q \]

Where:

a.  \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b.  \( C_{d-1} \) is the daily corporate rate (defined in Section 13.C.7G) for the business day immediately preceding the premium determination date; and

c.  \( C_q \) is the average daily corporate rate (defined in Section 13.C.8H) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate (\( I_d \)) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4.  Reference Rate

Reference rates are updated quarterly as described below:

a.  The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b.  Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c.  The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 13.C.9I) effective for the calendar year in which the premium determination date falls.

5.  Spread

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a.  Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.
b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.1) effective for the calendar year in which the premium determination date falls.

6. Default costs for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 13.C.9I) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAMLC1A0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAMLC2A0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAMLC3A0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAMLC4A0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAMLC7A0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAMLC8A0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 13.C.9I) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:
a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 13.C.7.aG.1].

b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 13.C.9I) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating I_q in Section 13.C.3.e5.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

Weight Table 1

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:

i. Bucket A:
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   b) Five-year certain only.

ii. Bucket B:
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   b) 10-year certain only.

iii. Bucket C:
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   c) 15-year certain only.

iv. Bucket D:

© 2022 National Association of Insurance Commissioners
a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.

b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for individual annuities for males (ANB).

c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d4.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c3.)

e. The present value of each summed cash-flow group in Step d4 is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

a) Column 1 of Table 4 is identical to column 1 of Table 1.

b) Column 2 of Table 4 is 50% of column 2 of Table 1.

c) Column 3 of Table 4 is identical to column 2 of Table 4.

d) Column 4 of Table 4 is 50% of column 3 of Table 1.

e) Column 5 of Table 4 is identical to column 4 of Table 4.

f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 13.A.2.1B.9), the following apply:
a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

**Guidance Note:** Under some group annuity contracts, certificates may be purchased on different dates.

b. In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

**Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.
This page intentionally left blank
Valuation Manual Section II. Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for fixed annuity contracts issued prior to 1/1/2024 are those requirements as found in VM-A and VM-C as applicable, with the exception of the minimum requirements for the valuation interest rate for single premium immediate annuity contracts, and other similar contracts, issued after Dec. 31, 2017, including those fixed payout annuities emanating from host contracts issued on or after Jan. 1, 2017, and on or before Dec. 31, 2017. The maximum valuation interest rate requirements for those contracts and fixed payout annuities are defined in Section 13 of VM-22, Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves.

C.D. Minimum reserve requirements for fixed annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 12 of VM-22.

E. The below principles may serve as key considerations for assessing whether VM-21 or VM-22 requirements apply:

1. Index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for application of VM-22 requirements:
   a. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.
   b. Credits a rate of interest under the contract that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

   **Guidance Note:** Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

2. Index-linked or modified guaranteed annuity contracts that do not satisfy either of the two conditions listed above in Paragraph E.1.i and E.1.ii may be a key consideration for application of VM-21 requirements.
Subsection 6: Riders and Supplemental Benefits

Drafting Note: All revisions shown in this section are in comparison to Subsection 6 in Section II of the Valuation Manual.

Guidance Note: Policiesy designs, or contracts with riders and supplemental benefits which are created to simply disguise benefits riders subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, VM-20 Section 3.A.1 or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, annuity product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be included with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraph C above including, but not limited to, Guaranteed Minimum Accumulation Benefits, Guaranteed Minimum Death Benefits, Guaranteed Minimum Income Benefits, Guaranteed Minimum Withdrawal Benefits, Guaranteed Lifetime Income Benefits, Guaranteed Lifetime Withdrawal Benefits, Guaranteed Payout Annuity Floors, Waiver of Surrender Charges, Return of Premium, Systematic Withdrawal Benefits under Required Minimum Distributions, and all similar guaranteed benefits shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

D.E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be included with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.

2. The rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.

3. The rider or supplemental benefit premium, charge, value or benefits are determined by referencing the rider or supplemental benefit features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.
E.F. If a term life insurance rider on the named insured[s] on the base life insurance policy does not meet the conditions of Paragraph DE above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.

E.G. For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through EF above, the riders or supplemental benefits may be included with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

E.H. Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.
July 16, 2021
Bruce Sartain, Chair
Valuation Manual (VM)-22 (A) Subgroup
Life Actuarial (A) Task Force
National Association of Insurance Commissioners (NAIC)

Dear Mr. Sartain,

The American Academy of Actuaries\(^1\) Annuity Reserves and Capital Work Group (ARCWG) presented a fixed annuity principle-based reserving (PBR) framework proposal to the VM-22 Subgroup during its October 21, 2020 meeting. This document provides ARCWG’s initial draft of NAIC Valuation Manual Section II and VM-22 requirements associated with the ARCWG proposal. We ask for the VM-22 Subgroup’s consideration of the language herein as a foundation for further drafting efforts, in your efforts to advance toward an NAIC fixed annuity PBR framework.

Please let us know if you have any follow-up inquiries in response to this document. Again, we appreciate the opportunity to propose the fixed annuity framework and all of the efforts made by the VM-22 Subgroup to focus on this topic.

Sincerely,
Ben Slutsker
Chairperson, Annuity Reserves and Capital Work Group
American Academy of Actuaries

---

\(^1\) The American Academy of Actuaries is a 19,500-member professional association whose mission is to serve the public and the U.S. actuarial profession. For more than 50 years, the Academy has assisted public policymakers on all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues. The Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.
VM-22 PBR: Requirements for Principle-Based Reserves for Non-Variable Annuities

Drafting Overview: This document is the ARCWG-proposed draft Valuation Manual wording for VM-22 PBR for non-variable annuities. The edits reflected in this draft are made in association with the recommendations in the Annuity Reserves Work Group-proposed VM-22 presentation, exposed by the VM-22 Subgroup in October 2020. Each section shows editorial mark-ups compared to existing VM-20 or VM-21 wording, which is included as a draft note at the beginning of each section (with the only exceptions being Sections 1 and 2 that do not contain mark-ups to existing Valuation Manual wording).

Valuation Manual Section II. Reserve Requirements ............................................. 71
Subsection 2: Annuity Products ........................................................................... 71
Subsection 6: Riders and Supplemental Benefits .................................................. 72
Section 1: Background

A. Purpose

These requirements establish the minimum reserve valuation standard for non-variable annuity contracts as defined in Section 2.A and issued on or after 1/1/2024. For all contracts encompassed by the Scope, these requirements constitute the Commissioners Annuity Reserve Valuation Method (CARVM) and, for certain contracts, the Commissioners Reserve Valuation Method (CRVM).

**Guidance Note:** CRVM requirements apply to some group pension contracts.

B. Principles

The projection methodology used to calculate the stochastic reserve is based on the following set of principles. These principles should be followed when interpreting and applying the methodology in these requirements and analyzing the resulting reserves.

**Guidance Note:** The principles should be considered in their entirety, and it is required that companies meet these principles with respect to those contracts that fall within the scope of these requirements and are in force as of the valuation date to which these requirements are applied.

Principle 1: The objective of the approach used to determine the stochastic reserve is to quantify the amount of statutory reserves needed by the company to be able to meet contractual obligations in light of the risks to which the company is exposed with an element of conservatism consistent with statutory reporting objectives.

Principle 2: The calculation of the stochastic reserve is based on the results derived from an analysis of asset and liability cash flows produced by the application of a stochastic cash-flow model to equity return and interest rate scenarios. For each scenario, the greatest present value of accumulated deficiency is calculated. The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario. The methodology uses a projected total cash flow analysis by including all projected income, benefit, and expense items related to the business in the model and sets the stochastic reserve at a degree of confidence using the CTE measure applied to the set of scenario specific greatest present values of accumulated deficiencies that is deemed to be reasonably conservative over the span of economic cycles.

Principle 3: The implementation of a model involves decisions about the experience assumptions and the modeling techniques to be used in measuring the risks to which the company is exposed. Generally, assumptions are to be based on the conservative end of the confidence interval. The choice of a conservative estimate for each assumption may result in a distorted measure of the total risk. Conceptually, the choice of assumptions and the modeling decisions should be made so that the final result approximates what would be obtained for the
stochastic reserve at the required CTE level if it were possible to calculate results over the joint
distribution of all future outcomes. In applying this concept to the actual calculation of the
stochastic reserve, the company should be guided by evolving practice and expanding
knowledge base in the measurement and management of risk.

**Guidance Note:** The intent of Principle 3 is to describe the conceptual framework for setting
assumptions. Section 10 provides the requirements and guidance for setting contract holder
behavior assumptions and includes alternatives to this framework if the company is unable to
fully apply this principle.

**Principle 4:** While a stochastic cash-flow model attempts to include all real-world risks
relevant to the objective of the stochastic cash-flow model and relationships among the risks,
it will still contain limitations because it is only a model. The calculation of the stochastic
reserve is based on the results derived from the application of the stochastic cash-flow model
to scenarios, while the actual statutory reserve needs of the company arise from the risks to
which the company is (or will be) exposed in reality. Any disconnect between the model and
reality should be reflected in setting prudent estimate assumptions to the extent not addressed
by other means.

**Principle 5:** Neither a cash-flow scenario model nor a method based on factors calibrated to
the results of a cash-flow scenario model can completely quantify a company’s exposure to
risk. A model attempts to represent reality but will always remain an approximation thereto
and, hence, uncertainty in future experience is an important consideration when determining
the stochastic reserve. Therefore, the use of assumptions, methods, models, risk management
strategies (e.g., hedging), derivative instruments, structured investments or any other risk
transfer arrangements (such as reinsurance) that serve solely to reduce the calculated
stochastic reserve without also reducing risk on scenarios similar to those used in the actual
cash-flow modeling are inconsistent with these principles. The use of assumptions and risk
management strategies should be appropriate to the business and not merely constructed to
exploit “foreknowledge” of the components of the required methodology.

C. Risks Reflected

1. The risks reflected in the calculation of reserves under these requirements arise from actual
or potential events or activities that are both:
   a. Directly related to the contracts falling under the scope of these requirements or
      their supporting assets; and
   b. Capable of materially affecting the reserve.

2. Categories and examples of risks reflected in the reserve calculations include, but are not
necessarily limited to:
   a. Asset risks
      i. Credit risks (e.g., default or rating downgrades).
ii. Commercial mortgage loan roll-over rates (roll-over of bullet loans).

iii. Uncertainty in the timing or duration of asset cash flows (e.g., shortening (prepayment risk) and lengthening (extension risk)).

iv. Performance of equities, real estate, and Schedule BA assets.

v. Call risk on callable assets.

vi. Separate account fund performance.

vii. Risk associated with hedge instrument (includes basis, gap, price, parameter estimation risks, and variation in assumptions).

viii. Currency risk.

b. Liability risks

i. Reinsurer default, impairment, or rating downgrade known to have occurred before or on the valuation date.

ii. Mortality/longevity, persistency/lapse, partial withdrawal, and premium payment risks.

iii. Utilization risk associated with guaranteed living benefits.

iv. Anticipated mortality trends based on observed patterns of mortality improvement or deterioration, where permitted.

v. Annuitzation risks.

vi. Additional premium dump-ins or deposits (high interest rate guarantees in low interest rate environments).

vii. Applicable expense risks, including fluctuation maintenance expenses directly attributable to the business, future commission expenses, and expense inflation/growth.

c. Combination risks

i. Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above.

ii. Disintermediation risk (including such risk related to payment of surrender or partial withdrawal benefits).

iii. Risks associated with revenue-sharing income.

3. The risks not necessarily reflected in the calculation of reserves under these requirements are:
a. Those not associated with the policies or contracts being valued, or their supporting assets.

b. Determined to not be capable of materially affecting the reserve.

4. Categories and examples of risks not reflected in the reserve calculations include, but are not necessarily limited to:

   a. Asset risks

      i. Liquidity risks associated with sudden and significant levels of withdrawals and surrenders.

   b. Liability risks

      i. Reinsurer default, impairment or rating downgrade occurring after the valuation date.

      ii. Catastrophic events (e.g., epidemics or terrorist events).

      iii. Major breakthroughs in life extension technology that have not yet fundamentally altered recently observed mortality experience.

      iv. Significant future reserve increases as an unfavorable scenario is realized.

   c. General business risks

      i. Deterioration of reputation.

      ii. Future changes in anticipated experience (reparameterization in the case of stochastic processes), which would be triggered if and when adverse modeled outcomes were to actually occur.

      iii. Poor management performance.

      iv. The expense risks associated with fluctuating amounts of new business.

      v. Risks associated with future economic viability of the company.

      vi. Moral hazards.

      vii. Fraud and theft.

D. Specific Definitions for VM-22

Buffer Annuity
Interchangeable term for Registered Index-Linked Annuity (RILA). See definition for Registered Index-Linked Annuity below.
Deferred Income Annuity (DIA)
An annuity which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin one year or later after (or from) the issue date if the contract holder survives to a predetermined future age.

Fixed Indexed Annuity (FIA)
An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, typically with guaranteed principal.

Flexible Premium Deferred Annuity (FPDA)
An annuity with an account value established with a premium amount but allows for additional deposits to be paid into the annuity over time, resulting in an increase to the account value. The contract also has a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase.

Funding Agreement
A contract issued to an institutional investor (domestic and international non-qualified fixed income investors) that provides fixed or floating interest rate guarantees.

Guaranteed Investment Contract (GIC)
Insurance contract typically issued to a retirement plan (defined contribution) under which the insurer accepts a deposit (or series of deposits) from the purchaser and guarantees to pay a specified interest rate on the funds deposited during a specified period of time.

Index Credit Hedge Margin
A margin capturing the risk of inefficiencies in the company’s hedging program supporting index credits. This includes basis risk, persistency risk, and the risk associated with modeling decisions and simplifications. It also includes any uncertainty of costs associated with managing the hedging program and changes due to investment and management decisions.

Index Credit
Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to policy values that is linked to an index or indices. Amounts credited to the policy resulting from a floor on an index account are included.

Index Crediting Strategy
The strategy defined in a contract to determine index credits for a contract. This refers to underlying index, index parameters, date, timing, and other elements of the crediting method.

Index Parameter
Cap, floor, participation rate, spreads, or other features describing how the contract utilizes the index.

Longevity Reinsurance
An agreement, typically a reinsurance arrangement covering one or more group or individual annuity contracts, under which an insurance company assumes the longevity risk associated with
periodic payments made to specified annuitants under one or more immediate or deferred payout annuity contracts. A common example is participants in one or more underlying retirement plans.

Typically, the reinsurer pays a portion of the actual benefits due to the underlying annuitants (or, in some cases, a pre-agreed amount per annuitant), while the ceding insurance company retains the assets supporting the reinsured annuity payments and pays periodic, ongoing premiums to the reinsurer over the expected lifetime of benefits paid to the specified annuitants. Such agreements may contain net settlement provisions such that only one party makes ongoing cash payments in a particular period. Under these agreements, longevity risk may be transferred on either a permanent basis or for a prespecified period of time, and these agreements may or may not permit early termination.

Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition. In particular, contracts under which payments are made based on the aggregate mortality experience of a population of lives which are not covered by an underlying group or individual annuity contract (e.g., mortality index-based longevity swaps) are not included in this definition.

**Market Value Adjustment (MVA) Annuity**
An annuity with an account value where withdrawals and full surrenders are subject to adjustments based on interest rates or index returns at the time of withdrawal/surrender. There could be ceilings and floors on the amount of the market-value adjustment.

**Modified Guaranteed Annuity (MGA)**
A type of market-value adjusted annuity contract where the underlying assets are held in an insurance company separate account and the value of which are guaranteed if held for specified periods of time. The contract contains nonforfeiture values that are based upon a market-value adjustment formula if held for shorter periods.

**Multiple Year Guaranteed Annuity (MYGA)**
A type of fixed annuity that provides a pre-determined and contractually guaranteed interest rate for specified periods of time, after which there is typically an annual reset or renewal of a multiple year guarantee period.

**Pension Risk Transfer (PRT) Annuity**
An annuity, typically a group contract or reinsurance agreement, issued by an insurance company providing periodic payments to annuitants receiving immediate or deferred benefits from one or more retirement plans. Typically, the insurance company holds the assets supporting the benefits, which may be held in the general or separate account, and retains not only longevity risk but also asset risks (e.g., credit risk and reinvestment risk).

**Registered Index-Linked Annuity (RILA)**
An annuity with an account value where the contract holder has the option for a portion or all of the account value to grow at a rate linked to an external index, similar to a Fixed Indexed Annuity, but with downside risk exposure that may not guarantee full principal repayment. These contracts may include a cap on upside returns, and may also include a floor on downside returns which may be below zero percent.
Single Premium Immediate Annuity (SPIA)
An annuity purchased with a single premium amount which guarantees a periodic payment for the life of the annuitant or a term certain and payments begin within one year after (or from) the issue date.

Single Premium Deferred Annuity (SPDA)
An annuity with an account value established with a single premium amount that grows with a guaranteed interest rate during the accumulation phase and has guaranteed mortality and interest rates applicable at the time of conversion to the payout phase. May also include cases where the premium is accepted for a limited amount of time early in the contract life, such as only in the first duration.

Stable Value Contract
A contract that provides limited investment guarantees, typically preserving principal while crediting steady, positive returns and protecting against losses or declines in yield. Underlying asset portfolios typically consist of fixed income securities, which may sit in the insurer’s general account, a separate account, or in a third-party trust. These contracts often support defined contribution or defined benefit retirement plan liabilities.

Structured Settlement Contract (SSC)
A contract that provides periodic benefits and is purchased with a single premium amount stemming from various types of claims pertaining to court settlements or out-of-court settlements from tort actions arising from accidents, medical malpractice, and other causes. Adverse mortality is typically expected for these contracts.

Synthetic GIC
Contract that simulates the performance of a traditional GIC through a wrapper, swap, or other financial instruments, with the main difference being that the assets are owned by the policyholder or plan trust.

Term Certain Payout Annuity
A contract issued, which offers guaranteed periodic payments for a specified period of time, not contingent upon mortality or morbidity of the annuitant.

Two-Tiered Annuity
A deferred annuity with two tiers of account values. One, with a higher accumulation interest rate, is only available for annuitization or death. The other typically contains a lower accumulation interest rate, and is only available upon surrender.
Section 2: Scope and Effective Date

A. Scope

Subject to the requirements of this VM-22 are annuity contracts, certificates and contract features, whether group or individual, including both life contingent and term-certain-only, directly written or assumed through reinsurance issued on or after 1/1/2024, with the exception of contracts or benefits listed below.

Products out of scope include:

- Contracts or benefits that are subject to VM-21 (such as variable annuities, RILAs, buffer annuities, and structured annuities)
- GICs
- Synthetic GICs
- Stable Value Contracts
- Funding Agreements

Products in scope of VM-22 include fixed annuities which consist of, but are not limited to, the following list:

- **Account Value Based Annuities**
  - Deferred Annuities (SPDA & FPDA)
  - Multi-Year Guarantee Annuities (MYGA)
  - Fixed Indexed Annuities (FIA)
  - Market-Value Adjustments (MVA)
  - Two-tiered Annuities
  - Guarantees/Benefits/Riders on Fixed Annuity Contracts

- **Payout Annuities**
  - Single Premium Immediate Annuities (SPIA)
  - Deferred Income Annuities (DIA)
  - Term Certain Payout Annuity
  - Pension Risk Transfer Annuities (PRT)
  - Structured Settlement Contracts (SSC)
  - Longevity Reinsurance

The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.

B. Effective Date & Transition

**Effective Date**

These requirements apply for valuation dates on or after January 1, 2024.

**Transition**

A company may elect to establish minimum reserves pursuant to applicable requirements in VM-A and VM-C for business otherwise subject to VM-22 PBR requirements and issued during the
first three years following the effective date of VM-22 PBR. If a company during the three years elects to apply VM-22 PBR to a block of such business, then a company must continue to apply the requirements of VM-22 PBR for future issues of this business. Irrespective of the transition date, a company shall apply VM-22 PBR requirements to applicable blocks of business on a prospective basis starting at least three years after the effective date.
Section 3: Reserve Methodology

A. Aggregate Reserve

The aggregate reserve for contracts falling within the scope of these requirements shall equal the stochastic reserve (following the requirements of Section 4) less any applicable PIMR for all contracts not valued under applicable requirements in VM-A and VM-C, plus the reserve for any contracts valued under applicable requirements in VM-A and VM-C.

**Guidance Note:** Contracts valued under applicable requirements in VM-A and VM-C are ones that pass the exclusion test and elect to not model PBR stochastic reserves, per the requirements in Section 3.E.

B. Impact of Reinsurance Ceded

All components in the aggregate reserve shall be determined post-reinsurance ceded, that is net of any reinsurance cash flows arising from treaties that meet the statutory requirements that allow the treaty to be accounted for as reinsurance. A pre-reinsurance ceded reserve also needs to be determined by ignoring all reinsurance cash flows (costs and benefits) in the reserve calculation.

C. To Be Determined

D. The Stochastic Reserve

1. The stochastic reserve shall be determined based on asset and liability projections for the contracts falling within the scope of these requirements, excluding those contracts valued using the methodology pursuant to applicable requirements in VM-A and VM-C, over a broad range of stochastically generated projection scenarios described in Section 8 and using prudent estimate assumptions as required in Section 3.F herein.

2. The stochastic reserve amount for any group of contracts shall be determined as CTE70 of the scenario reserves following the requirements of Section 4, with the exception of groups of contracts for which a company elects the Deterministic Certification Option in Section 7.E, which shall be determined as the scenario reserve following the requirements of Section 4.

3. The reserve may be determined in aggregate across various groups of contracts as a single model segment when determining the stochastic reserve if the business and risks are not managed separately or are part of the same integrated risk management program. Aggregation is permitted if a resulting group of contracts (or model segment) follows the listed principles:

   a. Aggregate in a manner that is consistent with the company’s risk management strategy and reflects the likelihood of any change in risk offsets that could arise from shifts between product types, and

   b. Using prudent actuarial judgement, consider the following elements when aggregating groups of contracts: whether groups of contracts are part of the same portfolio (or different portfolios that interact), same integrated risk management system, administered/managed together

4. Do not aggregate groups of contracts for which the company elects to use the Deterministic Certification Option in Section 7.E with any groups of contracts that do not use such option.
5. To the extent that these limits on aggregation result in more than one model segment, the stochastic reserve shall equal the sum of the stochastic reserve amounts computed for each model segment and scenario reserve amounts computed for each model segment for which the company elects to use the Deterministic Certification Option in Section 7.E.

E. Exclusion Test

1. To the extent that certain groups of contracts pass one of the defined stochastic exclusion tests in Section 7.B, these groups of contracts may be valued using the methodology pursuant to applicable requirements in VM-A and VM-C, with the statutory maximum valuation rate for immediate annuities specified in Section 13.

   a. For dividend-paying contracts, a dividend liability shall be established upon following requirements in VM-A and VM-C, as described above, for the base contract.

Guidance Note: The intention of contracts that pass the stochastic exclusion test is to provide the option to value contracts under VM-A and VM-C. This may apply to pre-PBR CARVM requirements in accordance with Actuarial Guideline XXXIII (AG33) methodology with type A, B, C rates for SPIAs issued before 2018; AG33 methodology with pre-PBR VM-22 rates for SPIAs issued on/after 2018; Actuarial Guideline XXXV (AG35) pre-PBR methodology for Fixed Indexed Annuities; and AG33 methodology (with interest rate updates for modernization initiatives on new contracts) for non-SPIAs.

2. The approach for grouping contracts when performing the exclusion tests should follow the same principles that underlie the aggregation approach for model segments discussed for Stochastic Reserves in Section D above.

F. Allocation of the Aggregate Reserve to Contracts

The aggregate reserve shall be allocated to the contracts falling within the scope of these requirements using the method outlined in Section 12.

G. Prudent Estimate Assumptions:

1. With respect to the Stochastic Reserve in Section 3.C, the company shall establish the prudent estimate assumption for each risk factor in compliance with the requirements in Section 12 of Model #820 and must periodically review and update the assumptions as appropriate in accordance with these requirements.

2. The qualified actuary, to whom responsibility for this group of contracts is assigned, shall annually review relevant emerging experience for the purpose of assessing the appropriateness of the anticipated experience assumption. If the results of statistical testing or other testing indicate that previously anticipated experience for a given factor is inadequate, then the qualified actuary shall set a new, adequate, anticipated experience assumption for the factor.

3. To determine the prudent estimate assumptions, the stochastic reserve shall also follow the requirements in Sections 4 and 9 for asset assumptions, Section 10 for policyholder behavior assumptions, and Section 11 for mortality assumptions.
Section 4: Determination of Stochastic Reserve

A. Projection of Accumulated Deficiencies

1. General Description of Projection

The projection of accumulated deficiencies shall be made ignoring federal income tax in both cash flows and discount rates, and it shall reflect the dynamics of the expected cash flows for the entire group of contracts, reflecting all product features, including any guarantees provided under the contracts using prudent estimate liability assumptions defined in Sections 10 and 11 and asset assumptions defined in Section 4.D. The company shall project cash flows including the following:

a. Revenues received by the company including gross premiums received from the policyholder (including any due premiums as of the projected start date).

b. All material benefits projected to be paid to policyholders—including, but not limited to, death claims, surrender benefits and withdrawal benefits—reflecting the impact of all guarantees and adjusted to take into account amounts projected to be charged to account values on general account business. Any guarantees, in addition to market value adjustments assessed on projected withdrawals or surrenders, shall be taken into account.

Guidance Note: Amounts charged to account values on general account business are not revenue; examples include rider charges and expense charges.

c. Non-Guaranteed Elements (NGE) cash flows as described in Section 10.J.

d. Insurance company expenses (including overhead and investment expense), commissions, contractual fees and charges, and revenue-sharing income received by the company (net of applicable expenses).

e. Net cash flows associated with any reinsurance.

f. Cash flows from hedging instruments as described in Section 4.A.4.

g. Cash receipts or disbursements associated with invested assets (other than policy loans) as described in Section 4.D.4, including investment income, realized capital gains and losses, principal repayments, asset default costs, investment expenses, asset prepayments, and asset sales.

h. If modeled explicitly, cash flows related to policy loans as described in Section 10.I.2, including interest income, new loan payments and principal repayments.

Guidance Note: Future net policy loan cash flows include: policy loan interest paid in cash plus repayments of policy loan principal, including repayments occurring at death or surrender (note that the future benefits in Section 4.A.1.b are before consideration of policy...
loans), less additional policy loan principal (but excluding policy loan interest that is added to the policy loan principal balance).

2. Grouping of Index Crediting Strategies

Index crediting strategies may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy. In assigning each index crediting strategy to a grouping for projection purposes, the fundamental characteristics of the index crediting strategy shall be reflected, and the parameters shall have the appropriate relationship to the stochastically generated projection scenarios described in Section 8. The grouping shall reflect characteristics of the efficient frontier (i.e., returns generally cannot be increased without assuming additional risk).

Index accounts sharing similar index crediting strategies may also be grouped for modeling to an appropriately crafted proxy strategy normally expressed as a linear combination of recognized market indices, sub-indices or funds, in order to develop the investment return paths and associated interest crediting. Each index crediting strategy’s specific risk characteristics, associated index parameters, and relationship to the stochastically generated scenarios in Section 8 should be considered before grouping or assigning to a proxy strategy. Grouping and/or development of a proxy strategy may not be done in a manner that intentionally understates the resulting reserve.

3. Model Cells

Projections may be performed for each contract in force on the date of valuation or by assigning contracts into representative cells of model plans using all characteristics and criteria having a material impact on the size of the reserve. Assigning contracts to model cells may not be done in a manner that intentionally understates the resulting reserve.

4. Modeling of Hedges

a. For a company that does not have a future hedging program tied directly to the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. The company shall not consider the cash flows from any future hedge purchases or any rebalancing of existing hedge assets in its modeling.

ii. Existing hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the starting assets. The hedge assets may then be considered in one of two ways:

   a) Include the asset cash flows from any contractual payments and maturity values in the projection model; or

   b) No hedge positions—in which case the hedge positions held on the valuation date are replaced with cash and/or other general account assets in an amount equal to the aggregate market value of these hedge positions.
Guidance Note: If the hedge positions held on the valuation date are replaced with cash, then as with any other cash, such amounts may then be invested following the company’s investment strategy.

A company may switch from method a) to method b) at any time, but it may only change from b) to a) with the approval of the domiciliary commissioner.

b. For a company that has a future hedging program tied directly to the contracts falling under the scope of VM-22 stochastic reserve requirements:

i. For a hedging program with hedge payoffs that offset interest credits associated with indexed interest strategies (indexed interest credits):

a) In modeling cash flows, the company shall include the cash flows from future hedge purchases or any rebalancing of existing hedge assets that are intended solely to offset interest credits to policyholders.

b) Existing hedging instruments that are currently held by the company for this purpose in support of the contracts falling under the scope of these requirements shall be included in the starting assets. Existing hedging instruments that are currently held by the company for any other purpose should be modeled consistently with the requirements of Section 4.A.4.a.ii.

c) An Index Credit Hedge Margin for these instruments shall be reflected by reducing index interest credit hedge payoffs by a margin multiple that shall be justified by sufficient and credible company experience and be no less than [X%] multiplicatively of the interest credited. In the absence of sufficient and credible company experience, a margin of [Y%] shall be assumed. There is no cap on the index credit hedge margin if company experience indicates actual error is greater than [Y%]. It is permissible to substitute stress-testing for sufficient and credible experience if such stress-testing comprehensively considers a robust range of future market conditions.

ii. For a company that hedges any contractual obligation or risks other than indexed interest credits, the detailed requirements for the modeling of hedges are defined in Section 9. The following requirements do not supersede the detailed requirements.

a) The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the projections used in the determination of the stochastic reserve.

b) The projections shall take into account the appropriate costs and benefits of hedge positions expected to be held in the future.
Because models do not always accurately portray the results of hedge programs, the company shall, through back-testing and other means, assess the accuracy of the hedge modeling. The company shall determine a stochastic reserve as the weighted average of two CTE values: first, a CTE70 (“best efforts”) representing the company’s projection of all of the hedge cash flows, including future hedge purchases, and a second CTE70 (“adjusted”) which shall use only hedge assets held by the company on the valuation date and only future hedge purchases associated with indexed interest credited. These are discussed in greater detail in Section 9.

c) Consistent with Section 4.A.4.b.i., the index credit hedge margin for instruments associated with indexed interest credited shall be reflected by reducing hedge payoffs by a margin multiple as defined in Section 4.A.4.b.i.c).

d) The use of products not falling under the scope of these requirements as a hedge shall not be recognized in the determination of accumulated deficiencies.

Guidance Note: Section 4.A.4.b.i is intended to address common situations for products with index crediting strategies where the company only hedges index credits or clearly separates index credit hedging from other hedging. In this case the hedge positions are considered similarly to other fixed income assets supporting the contracts, and a margin is reflected rather than modeling using a CTE70 adjusted run with no future hedge purchases. If a company has a more comprehensive hedge strategy combining index credits, guaranteed benefit, and other risks (e.g., full fair value or economic hedging), an appropriate and documented bifurcation method should be used in the application of sections 4.A.4.b.i and 4.A.4.b.ii above for the hedge modeling and justification. Such bifurcation methods may quantify the specific risk exposure attributable to index credit liabilities versus other liabilities such as guaranteed living benefits, and apply such for the basis for allocation.

Guidance Note: The requirements of Section 4.A.4 govern the determination of reserves for annuity contracts and do not supersede any statutes, laws or regulations of any state or jurisdiction related to the use of derivative instruments for hedging purposes and should not be used in determining whether a company is permitted to use such instruments in any state or jurisdiction.

5. Revenue Sharing

If applicable, projections of accumulated deficiencies may include income from projected future revenue sharing, net of applicable projected expenses (net revenue-sharing income) if each of the requirements set forth in VM 21 Section 4.A.5 are met.

6. Length of Projections

Projections of accumulated deficiencies shall be run for as many future years as needed so that no materially greater reserve value would result from longer projection periods.
7. Interest Maintenance Reserve (IMR)

The IMR shall be handled consistently with the treatment in the company’s cash flow testing, and the amounts should be adjusted to a pre-tax basis.

B. Determination of Scenario Reserve

1. For a given scenario, the scenario reserve shall be determined using one of two methods described below:

   a) The starting asset amount plus the greatest present value, as of the projection start date, of the projected accumulated deficiencies; or

   **Guidance Note:** The greatest present value of accumulated deficiencies can be negative.

   b) The direct iteration method, where the scenario reserve is determined by solving for the amount of starting assets which, when projected along with all contract cash flows, result in the defeasement of all projected future benefits and expenses at the end of the projection horizon with no positive accumulated deficiencies at the end of any projection year during the projection period.

   The scenario reserve for any given scenario shall not be less than the cash surrender value in aggregate on the valuation date for the group of contracts modeled in the projection.

2. Discount Rates

In determining the scenario reserve, unless using the direct iteration method pursuant to Section 4.B.1.b, the accumulated deficiencies shall be discounted at the NAER on additional assets, as defined in Section 4.B.3.

3. Determination of NAER on Additional Invested Asset Portfolio

   a. The additional invested asset portfolio for a scenario is a portfolio of general account assets as of the valuation date, outside of the starting asset portfolio, that is required in that projection scenario so that the projection would not have a positive accumulated deficiency at the end of any projection year. This portfolio may include only (i) General Account assets available to the company on the valuation date that do not constitute part of the starting asset portfolio; and (ii) cash assets.

   **Guidance Note:**

   Additional invested assets should be selected in a manner such that if the starting asset portfolio were revised to include the additional invested assets, the projection would not be expected to experience any positive accumulated deficiencies at the end of any projection year.

   It is assumed that the accumulated deficiencies for this scenario projection are known.

   b. To determine the NAER on additional invested assets for a given scenario:
i. Project the additional invested asset portfolio as of the valuation date to the end of the projection period,
   a) Investing any cash in the portfolio and reinvesting all investment proceeds using the company’s investment policy.
   b) Excluding any liability cash flows.
   c) Incorporating the appropriate returns, defaults and investment expenses for the given scenario.

ii. If the value of the projected additional invested asset portfolio does not equal or exceed the accumulated deficiencies at the end of each projection year for the scenario, increase the size of the initial additional invested asset portfolio as of the valuation date, and repeat the preceding step.

iii. Determine a vector of annual earned rates that replicates the growth in the additional invested asset portfolio from the valuation date to the end of the projection period for the scenario. This vector will be the NAER for the given scenario.

iv. If the depletion of assets within the projection results in an unreasonably high negative NAER upon borrowing, the NAER may be set to the assumed cost of borrowing associated with each projected time period, in accordance with Section 4.D.3.c, as a safe harbor.

**Guidance Note:** There are multiple ways to select the additional invested asset portfolio at the valuation date. Similarly, there are multiple ways to determine the earned rate vector. The company shall be consistent in its choice of methods, from one valuation to the next.

C. Projection Scenarios

1. Number of Scenarios

   The number of scenarios for which the scenario reserve shall be computed shall be the responsibility of the company, and it shall be considered to be sufficient if any resulting understatement in the stochastic reserve, as compared with that resulting from running additional scenarios, is not material.

2. Economic Scenario Generation

   Treasury Department interest rate curves, as well as investment return paths for index funds, equities, and fixed income assets shall be determined on a stochastic basis using the methodology described in Section 8. If the company uses a proprietary generator to develop scenarios, the company shall demonstrate that the resulting scenarios meet the requirements described in Section 8.
D. Projection of Assets

1. Starting Asset Amount
   a. For the projections of accumulated deficiencies, the value of assets at the start of the projection shall be set equal to the approximate value of statutory reserves at the start of the projection plus the allocated amount of PIMR attributable to the assets selected. Assets shall be valued consistently with their annual statement values. The amount of such asset values shall equal the sum of the following items, all as of the start of the projection:
      i. Any hedge instruments held in support of the contracts being valued; and
      ii. An amount of assets held in the general account equal to the approximate value of statutory reserves as of the start of the projections less the amount in (i).
   b. If the amount of initial general account assets is negative, the model should reflect a projected interest expense. General account assets chosen for use as described above shall be selected on a consistent basis from one reserve valuation hereunder to the next.

2. Valuation of Projected Assets
   For purposes of determining the projected accumulated deficiencies, the value of projected assets shall be determined in a manner consistent with their value at the start of the projection. For assets assumed to be purchased during a projection, the value shall be determined in a manner consistent with the value of assets at the start of the projection that have similar investment characteristics. However, for derivative instruments that are used in hedging and are not assumed to be sold during a particular projection interval, the company may account for them at an amortized cost in an appropriate manner elected by the company.

   **Guidance Note:** Accounting for hedge assets should recognize any methodology prescribed by a company’s state of domicile.

3. General Account Assets
   a. General account assets shall be projected, net of projected defaults, using assumed investment returns consistent with their book value and expected to be realized in future periods as of the date of valuation. Initial assets that mature during the projection and positive cash flows projected for future periods shall be invested in a manner that is representative of and consistent with the company’s investment policy, subject to the following requirements:
      i. The final maturities and cash flow structures of assets purchased in the model, such as the patterns of gross investment income and principal repayments or a fixed or floating rate interest basis, shall be determined by the company as part of the model representation;
ii. The combination of price and structure for fixed income investments and derivative instruments associated with fixed income investments shall appropriately reflect the projected Treasury Department curve along the relevant scenario and the requirements for gross asset spread assumptions stated below;

iii. For purchases of public non-callable corporate bonds, follow the requirements defined in VM-20 Sections 7.E, 7.F and 9.F. The prescribed spreads reflect current market conditions as of the model start date and grade to long-term conditions based on historical data at the start of projection year four;

iv. For transactions of derivative instruments associated with fixed income investments, reflect the prescribed assumptions in VM-20 Section 9.F for interest rate swap spreads;

v. For purchases of other fixed income investments, if included in the model investment strategy, set assumed gross asset spreads over U.S. Treasuries in a manner that is consistent with, and results in reasonable relationships to, the prescribed spreads for public non-callable corporate bonds and interest rate swaps.

b. Notwithstanding the above requirements, the model investment strategy and any non-prescribed asset spreads shall be adjusted as necessary so that the aggregate reserve is not less than that which would be obtained by substituting an alternative investment strategy in which all fixed income reinvestment assets are public non-callable corporate bonds with gross asset spreads, asset default costs, and investment expenses by projection year that are consistent with a credit quality blend of:

i. 5% Treasury

ii. 15% PBR credit rating 3 (Aa2/AA)

iii. 40% PBR credit rating 6 (A2/A)

iv. 40% PBR credit rating 9 (Baa/BBB)

c. Any disinvestment shall be modeled in a manner that is consistent with the company’s investment policy and that reflects the company’s cost of borrowing where applicable, provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period, taking into account duration, ratings, and other attributes of the borrowing mechanism. Gross asset spreads used in computing market values of assets sold in the model shall be consistent with, but not necessarily the same as, the gross asset spreads in Section 4.D.4.a.ii and Section 4.D.4.a.iv, recognizing that initial assets that mature during the projection may have different characteristics than modeled reinvestment assets.
Guidance Note: This limitation is being referred to Life Actuarial (A) Task Force for review. The simple language above “provided that the assumed cost of borrowing is not lower than the rate at which positive cash flows are reinvested in the same time period” is not intended to impose a literal requirement. It is intended to reflect a general concept to prevent excessively optimistic borrowing assumptions. It is recognized that borrowing parameters and rules can be complicated, such that modeling limitations may not allow for literal compliance, in every time step, as long as the reserve is not materially affected. However, if the company is unable to fully apply this restriction, prudence dictates that a company shall not allow borrowing assumptions to materially reduce the reserve.

4. Cash Flows from Invested Assets

a. Cash flows from general account fixed income assets, including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Model gross investment income and principal repayments in accordance with the contractual provisions of each asset and in a manner consistent with each scenario.

ii. Reflect asset default costs as prescribed in VM-20 Section 9.F and anticipated investment expenses through deductions to the gross investment income.

iii. Model the proceeds arising from modeled asset sales and determine the portion representing any realized capital gains and losses.

iv. Reflect any uncertainty in the timing and amounts of asset cash flows related to the paths of interest rates, equity returns or other economic values directly in the projection of asset cash flows. Asset defaults are not subject to this requirement, since asset default assumptions must be determined by the prescribed method in VM-20 Sections 7.E, 7.F and 9.F.

b. Cash flows from general account index funds and equity assets—i.e., non-fixed income assets having substantial volatility of returns, such as common stocks and real estate—including starting and reinvestment assets, shall be reflected in the projection as follows:

i. Determine the grouping for asset categories and the allocation of specific assets to each category in a manner that is consistent with that used for index crediting strategies, as discussed in Section 4.A.2.

ii. Project the gross investment return including realized and unrealized capital gains in a manner that is consistent with the stochastically generated scenarios.

iii. Model the timing of an asset sale in a manner that is consistent with the investment policy of the company for that type of asset. Reflect expenses through a deduction to the gross investment return using prudent estimate assumptions.
c. Cash flows for each projection interval for policy loan assets shall follow the requirements in Section 10.I.

E. Projection of Annuitization Benefits

1. Assumed Annuitization Purchase Rates

   a. For payouts specified at issue (such as single premium immediate annuities, deferred income annuities, and certain structured settlements), such payout rates shall reflect the payout rate specified in the contract.

   b. For purposes of projecting future elective annuitization benefits and withdrawal amounts from GMWBs, the projected annuitization purchase rates shall be determined assuming that market interest rates available at the time of election are the interest rates used to project general account assets, as determined in Section 4.D.4. In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.

2. Projected Election of GMIBs, GMWBs and Other Annuitization Options

For contracts projected to elect future annuitization options (including annuitizations stemming from the election of a GMIB) or for projections of GMWB benefits once the account value has been depleted, the projections may assume the contract will stay in force, the projected periodic payments are paid, and the associated maintenance expenses are incurred.

F. Frequency of Projection and Time Horizon

1. Use of an annual cash-flow frequency (“timestep”) is generally acceptable for benefits/features that are not sensitive to projection frequency. The lack of sensitivity to projection frequency should be validated by testing wherein the company should determine that the use of a more frequent—i.e., shorter—time step does not materially increase reserves. A more frequent time increment should always be used when the product features are sensitive to projection period frequency.

2. Care must be taken in simulating fee income and expenses when using an annual time step. It is also important that the frequency of the investment return model be linked appropriately to the projection horizon in the liability model. In particular, the horizon should be sufficiently long so as to capture the vast majority of costs (on a present value basis) from the scenarios.

   **Guidance Note:** As a general guide, the forecast horizon should not be less than 20 years.

G. Compliance with ASOPs

When determining a stochastic reserve, the analysis shall conform to the ASOPs as promulgated from time to time by the ASB.

Under these requirements, an actuary will make various determinations, verifications and certifications. The company shall provide the actuary with the necessary information sufficient to
permit the actuary to fulfill the responsibilities set forth in these requirements and responsibilities arising from each applicable ASOP.
Section 5: Reinsurance Ceded and Assumed

A. Treatment of Reinsurance Ceded in the Aggregate Reserve

1. Aggregate Reserve Pre- and Post-Reinsurance Ceded

As noted in Section 3.B, the aggregate reserve is determined both pre-reinsurance ceded and post-reinsurance ceded. Therefore, it is necessary to determine the components needed to determine the aggregate reserve—i.e., the stochastic reserve and/or the reserve amount valued using requirements in VM-A and VM-C, as applicable—on both bases. Sections 5.A.2 and 5.A.3 discuss adjustments to inputs necessary to determine these components on both a post-reinsurance ceded and a pre-reinsurance ceded basis. Note that due allowance for reasonable approximations may be used where appropriate.

2. Stochastic Reserve

   a. In order to determine the aggregate reserve post-reinsurance ceded, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve shall be determined reflecting the effects of reinsurance treaties that meet the statutory requirements that would allow the treaty to be accounted for as reinsurance within statutory accounting. This involves including, where appropriate, all projected reinsurance premiums or other costs and all reinsurance recoveries, where the reinsurance cash flows reflect all the provisions in the reinsurance agreement, using prudent estimate assumptions.

      i. All significant terms and provisions within reinsurance treaties shall be reflected. In addition, it shall be assumed that each party is knowledgeable about the treaty provisions and will exercise them to their advantage.

         Guidance Note: Renegotiation of the treaty upon the expiration of an experience refund provision or at any other time shall not be assumed if such would be beneficial to the company and not beneficial to the counterparty. This is applicable to both the ceding party and assuming party within a reinsurance arrangement.

      ii. If the company has knowledge that a counterparty is financially impaired, the company shall establish a margin for the risk of default by the counterparty. In the absence of knowledge that the counterparty is financially impaired, the company is not required to establish a margin for the risk of default by the counterparty.

      iii. A company shall include the cash flows from a reinsurance agreement or amendment in calculating the aggregate reserve if such qualifies for credit in compliance with Appendix A-791 of the Accounting Practices and Procedures Manual. If a reinsurance agreement or amendment does not qualify for credit for reinsurance but treating the reinsurance agreement or amendment as if it did so qualify would result in a reduction to the company’s surplus, then the company shall increase the minimum reserve by the absolute value of such reductions in surplus.

   b. In order to determine the stochastic reserve on a pre-reinsurance ceded basis, accumulated deficiencies, scenario reserves, and the resulting stochastic reserve shall be determined ignoring the effects of reinsurance ceded within the projections. Different approaches may be used to determine the starting assets on the ceded portion of the contracts, dependent upon the characteristics of a given treaty:

      i. For a standard coinsurance treaty, where the assets supporting the ceded liabilities were transferred to the assuming reinsurer, one acceptable approach involves a projection
based on using starting assets on the ceded portion of the policies that are similar to those 
supporting the retained portion of the ceded policies or supporting similar types of 
policies. Scaling up each asset supporting the retained portion of the contract is also an 
acceptable method.

Guidance Note: For standard pro rata insurance treaties (does not include experience refunds), 
where allocated expenses are similar to the renewal expense allowance, reflecting the quota share 
applied to the present value of future reinsurance cash flows pertaining to the reinsured block of 
business may be considered as a possible approach to determine the ceded reserves.

ii. Alternatively, a treaty may contain an identifiable portfolio of assets associated with the 
ceded liabilities. This could be the case for several forms of reinsurance: funds withheld 
coinsurance; modified coinsurance; coinsurance with a trust. To the extent these assets 
would be available to the cedant, an acceptable approach could involve modeling this portfolio of assets. To the extent that these assets were insufficient to defease the ceded liabilities, the modeling would partially default to the approach discussed for a standard 
coinsurance treaty. To the extent these assets exceeded what might be needed to defease 
the ceded liabilities (perhaps an over collateralization requirement in a trust), the 
inclusion of such assets shall be limited.

Guidance Note: Section 3.5.2 in ASOP No. 52, Principle-Based Reserves for Life Products under 
the NAIC Valuation Manual, provides possible methods for constructing a hypothetical pre-
reinsurance asset portfolio, if necessary, for purposes of the pre-reinsurance reserve calculation.

c. An assuming company shall use assumptions to project cash flows to and from ceding companies 
that reflect the assuming company’s experience for the business segment to which the reinsured 
policies belong and reflect the terms of the reinsurance agreement.

3. Reserve Determined Upon Passing the Exclusion Test

If a company passes the stochastic exclusion test and elects to use a methodology pursuant to applicable 
Sections VM-A and VM-C, as allowed in Section 3.E, it is important to note that the methodology 
produces reserves on a pre-reinsurance ceded basis. Therefore, the reserve must be adjusted for any 
reinsurance ceded accordingly. In addition, reserves valued under applicable Sections in VM-A and VM-
C, unadjusted for reinsurance, shall be applied to the contracts falling under the scope of these 
requirements to determine the aggregate reserve prior to reinsurance.

It should be noted that the pre-reinsurance and post-reinsurance reserves may result in different outcomes 
for the exclusion test. In particular, it is possible that the pre-reinsurance reserves would pass the relevant 
exclusion test (and allow the use of VM-A and VM-C) while the post-reinsurance reserves might not.

4. To Be Determined
Section 6: To Be Determined
Section 7: Exclusion Testing

A. Stochastic Exclusion Test Requirement Overview

1. The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation if the stochastic exclusion test (SET) is satisfied for that group of contracts. The company has the option to calculate or not calculate the SET.

   a. If the company does not elect to calculate the SET for one or more groups of contracts, or the company calculates the SET and fails the test for such groups of contracts, the reserve methodology described in Section 4 shall be used for calculating the aggregate reserve for those groups of contracts.

   b. If the company elects to calculate the SET for one or more groups of contracts, and passes the test for such groups of contracts, then the company shall choose whether or not to use the reserve methodology described in Section 4 for those groups of contracts. If the reserve methodology described in Section 4 is not used for one or more groups of contracts, then the company shall use the reserve methodology pursuant to applicable requirements in VM-A and VM-C to calculate the aggregate reserve for those groups of contracts.

   c. A company may not exclude a group of contracts from the stochastic reserve requirements if there are one or more future hedging programs associated with the contracts, with the exception of hedging programs solely supporting index credits as described in Section 9.A.1.

B. Types of Stochastic Exclusion Tests

Groups of contracts pass the SET if one of the following is met:

1. Stochastic Exclusion Ratio Test (SERT)—Annually the company demonstrates that the groups of contracts pass the SERT defined in Section 7.C.

2. Stochastic Exclusion Demonstration Test—In the first year and at least once every three calendar years thereafter, the company provides a demonstration in the PBR Actuarial Report as specified in Section 7.D.

3. SET Certification Method—For groups of contracts that do not have guaranteed living benefits, future hedging programs, or pension risk transfer business in the first year and at least every third calendar year thereafter, the company provides a certification by a qualified actuary that the group of contracts is not subject to material aggregate risk levels across interest rate risk, longevity risk, or asset return volatility risk (i.e., the risk on non-fixed-income investments having substantial volatility of returns, such as common stocks and real estate investments). The company shall provide the certification and documentation supporting the certification to the commissioner upon request.

Guidance Note: The qualified actuary should develop documentation to support the actuarial certification that presents his or her analysis clearly and in detail sufficient for another actuary to understand the analysis and reasons for the actuary’s conclusion that the group of contracts is not subject to material interest rate risk, longevity risk, or asset return volatility risk. Examples of methods a qualified actuary could use to support the actuarial certification include, but are not limited to:
C. Stochastic Exclusion Ratio Test

1. In order to exclude a group of contracts from the stochastic reserve requirements under the stochastic exclusion ratio test (SERT), a company shall demonstrate that the ratio of \(\frac{b-a}{a}\) is less than \([x]\)% where:

   a. \(a = \) the adjusted scenario reserve described in Paragraph C.2.a.i below using economic scenario 9, the baseline economic scenario, as described in Appendix 1.E of VM-20.

   b. \(b = \) the largest adjusted scenario reserve described in Paragraph C.2.b below under any of the other 15 economic scenarios described in Appendix 1.E of VM-20 under both \([95]\)% and \([105]\)% of anticipated experience mortality excluding margins.

**Guidance Note:** Note that the numerator should be the largest adjusted scenario reserve for scenarios other than the baseline economic scenario, minus the adjusted scenario reserve for the baseline economic scenario. This is not necessarily the same as the biggest difference from the adjusted scenario reserve for the baseline economic scenario, or the absolute value of the biggest difference from the adjusted scenario reserve for the baseline economic scenario, both of which could lead to an incorrect test result.

2. In calculating the ratio in subsection (1) above:

   a. The company shall calculate an adjusted scenario reserve for the group of contracts for the 16 scenarios that is equal to either (i) or (ii) below:

      i. The scenario reserve defined in Section 4, but with the following differences:

         a) Using anticipated experience assumptions with no margins, with the exception of mortality factors described in Paragraph C.1.b of this section.

         b) Using the interest rates and equity return assumptions specific to each scenario.

         c) Using NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows.
d) Shall reflect future mortality improvement in line with anticipated experience assumptions.

e) Shall not reflect correlation between longevity and economic risks.

ii. The gross premium reserve developed from the cash flows from the company’s asset adequacy analysis models, using the experience assumptions of the company’s cash-flow analysis, but with the following differences:

a) Using the interest rates and equity return assumptions specific to each scenario.

b) Using the mortality scalars described in Paragraph C.1.b of this section.

c) Using the methodology to determine NAER and discount rates defined in Section 4 specific to each scenario to discount the cash flows, but using the company’s cash-flow testing assumptions for default costs and reinvestment earnings.

b. The company shall use the most current 16 economic scenarios published by the NAIC. The methodology for creating these scenarios can be found in Appendix 1 of VM-20.

c. The company shall use assumptions within each scenario that are dynamically adjusted as appropriate for consistency with each tested scenario.

d. The company may not group together contract types with significantly different risk profiles for purposes of calculating this ratio.

e. If the company has reinsurance arrangements that are pro rata coinsurance and do not materially impact the interest rate risk, longevity risk, or asset return volatility in the contract, then the company may elect to not conduct the exclusion test under a pre-reinsurance-ceded basis upon determining the pre-reinsurance reserve-ceded aggregate reserve.

3. If the ratio calculated in this section is less than [x]% pre-non-proportional reinsurance, but is greater than [x]% post-non-proportional reinsurance, the group of contracts will still pass the SERT if the company can demonstrate that the sensitivity of the adjusted scenario reserve to economic scenarios is comparable pre- and post-non-proportional reinsurance.

a. An example of an acceptable demonstration:

i. For convenience in notation • \( SERT = \frac{b-a}{a} \) defined in Section 7.C.1 above

a) The pre-non-proportional reinsurance results are “gross of non-proportional,” with a subscript “gn,” so denoted \( SERT_{gn} \)

b) The post-non-proportional results are “net of non-proportional,” with subscript “nn,” so denoted \( SERT_{nn} \)
ii. If a block of business being tested is subject to one or more non-proportional reinsurance cessions as well as other forms of reinsurance, such as pro rata coinsurance, take “gross of non-proportional” to mean net of all prorata reinsurance but ignoring the non-proportional contract(s), and “net of non-proportional” to mean net of all reinsurance contracts. That is, treat non-proportional reinsurance as the last reinsurance in, and compute certain values below with and without that last component.

iii. So, if SERT\_gn \leq [x] but SERT\_nn > [x], then compute the largest percent increase in reserve (LPIR) = (b – a)/a, both “gross of non-proportional” and “net of non-proportional.”

\[
\text{LPIR}_{\text{gn}} = \frac{b_{\text{gn}} - a_{\text{gn}}}{a_{\text{gn}}}
\]

\[
\text{LPIR}_{\text{nn}} = \frac{b_{\text{nn}} - a_{\text{nn}}}{a_{\text{nn}}}
\]

Note that the scenario underlying b\_gn could be different from the scenario underlying b\_nn.

If SERT\_gn \times \text{LPIR}_{\text{nn}}/\text{LPIR}_{\text{gn}} < [x], then the block of contracts passes the SERT.

b. Another more qualitative approach is to calculate the adjusted scenario reserves for the 16 scenarios both gross and net of reinsurance to demonstrate that there is a similar pattern of sensitivity by scenario.

4. The SERT may not be used for a group of contracts if, using the current year’s data, (i) the stochastic exclusion demonstration test defined in Section 7.D had already been attempted using the method in this section and did not pass; or (ii) the qualified actuary had actively undertaken to perform the certification method in this section and concluded that such certification could not legitimately be made.

D. Stochastic Exclusion Demonstration Test

1. In order to exclude a group of contracts from the stochastic reserve requirements using the methodology in this section, the company must provide a demonstration in the PBR Actuarial Report in the first year and at least once every three calendar years thereafter that complies with the following:

a. The demonstration shall provide a reasonable assurance that if the stochastic reserve was calculated on a stand-alone basis for the group of contracts subject to the stochastic reserve exclusion, the resulting stochastic reserve for those groups of contracts would not be higher than the statutory reserve determined pursuant to the applicable requirements in VM-A and VM-C. The demonstration shall take into account whether changing conditions over the current and two subsequent calendar years would be likely to change the conclusion to exclude the group of contracts from the stochastic reserve requirements.

b. If, as of the end of any calendar year, the company determines the aggregate reserve for the group of contracts no longer adequately provides for all material risks, the exclusion shall be discontinued, and the company fails the SERT for those contracts.
c. The demonstration may be based on analysis from a date that precedes the valuation
date for the initial year to which it applies if the demonstration includes an
explanation of why the use of such a date will not produce a material change in the
outcome, as compared to results based on an analysis as of the valuation date.

d. The demonstration shall provide an effective evaluation of the residual risk exposure
remaining after risk mitigation techniques, such as derivative programs and
reinsurance.

2. The company may use one of the following or another method acceptable to the
insurance commissioner to demonstrate compliance with subsection 7.D.1 above:

a. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-
C is greater than the stochastic reserve calculated on a stand-alone basis.

b. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-
C is greater than the scenario reserve that results from each of a sufficient number of
adverse deterministic scenarios.

c. Demonstrate that the statutory reserve calculated in accordance with VM-A and VM-
C is greater than the stochastic reserve calculated on a stand-alone basis, but using a
representative sample of contracts in the stochastic reserve calculations.

d. Demonstrate that any risk characteristics that would otherwise cause the stochastic
reserve calculated on a stand-alone basis to exceed the statutory reserve calculated in
accordance with VM-A and VM-C, are not present or have been substantially
eliminated through actions such as hedging, investment strategy, reinsurance or
passing the risk on to the policyholder by contract provision.

E. Deterministic Certification Option

1. The company has the option to determine the stochastic reserve for a group of
contracts using a single deterministic economic scenario, subject to the following
conditions.

a. The company certifies that economic conditions do not materially influence
anticipated contract holder behavior for the group of policies. Examples of
contract holder options that are materially influenced by economic conditions
include surrender benefits, recurring premium payments, and guaranteed living
benefits.

b. The company certifies that the group of policies is not supported by a
reinvestment strategy that contains future hedge purchases.

c. The company must perform and disclose results from the stochastic exclusion
ratio test following the requirements in Section 7.C, thereby disclosing the
scenario reserve volatility across various economic scenarios.
d. The company must disclose a description of contracts and associated features in the certification.

Drafting Note: Consider revisiting Paragraph E.1.c to possibly either require i) falling below a preset threshold for the exclusion ratio test under a single longevity/mortality scenario; or ii) to pass the exclusion test if longevity is not included as part of the ratio test.

2. The stochastic reserve for the group of contracts under the Deterministic Certification Option is determined as follows:

a. Cash flows are projected in compliance with the applicable requirements in Section 4, Section 5, Section 10, and Section 11 of VM-22 over a single economic scenario (scenario 12 found in Appendix 1 of VM-20).

b. The stochastic reserve equals the scenario reserve following the requirements for Section 4.

Guidance Note: The Deterministic Certification Option is intended to provide a non-stochastic option for Single Premium Immediate Annuities (SPIAs) and similar payout annuity products that contain limited or no optionality in the asset and liability cash flow projections.
Section 8: To Be Determined (Scenario Generation for VM-21)
Section 9: Modeling Hedges under a Future Hedging Strategy

A. Initial Considerations

1. This section applies to modeling of hedges other than situations where the company (a) only hedges index credits, or (b) clearly separates index credit hedging from other hedging. In those situations, the modeling of hedges supporting index credits can be simplified including applying an index credit hedge margin, following the requirements in Section 4.A.4.b.i.

2. The appropriate costs and benefits of hedging instruments that are currently held by the company in support of the contracts falling under the scope of these requirements shall be included in the calculation of the stochastic reserve, determined in accordance with Section 3.D and Section 4.D.

3. The company shall take into account the costs and benefits of hedge positions expected to be held by the company in the future along each scenario. Company management is responsible for developing, documenting, executing and evaluating the investment strategy for future hedge purchases. Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than [6] months.

4. For this purpose, the investment assets refer to all the assets, including derivatives supporting covered products and guarantees. This also is referred to as the investment portfolio. The investment strategy is the set of all asset holdings at all points in time in all scenarios. The hedging portfolio, which also is referred to as the hedging assets, is a subset of the investment assets. The hedging strategy is the hedging asset holdings at all points in time in all scenarios. There is no attempt to distinguish what is the hedging portfolio and what is the investment portfolio in this section. Nor is the distinction between investment strategy and hedging strategy formally made here. Where necessary to give effect to the intent of this section, the requirements applicable to the hedging portfolio or the hedging strategy are to apply to the overall investment portfolio and investment strategy.

5. This particularly applies to restrictions on the reasonableness or acceptability of the models that make up the stochastic cash-flow model used to perform the projections, since these restrictions are inherently restrictions on the joint modeling of the hedging and non-hedging portfolio. To give effect to these requirements, they must apply to the overall investment strategy and investment portfolio.

B. Modeling Approaches

1. The analysis of the impact of the hedging strategy on cash flows is typically performed using either one of two types of methods as described below. Although a hedging strategy normally would be expected to reduce risk provisions, the nature of the hedging strategy and the costs to implement the strategy may result in an increase in the amount of the stochastic reserve otherwise calculated.

2. The fundamental characteristic of the first type of method, referred to as the “explicit method,” is that hedging positions and their resulting cash flows are included in the stochastic cash-flow model used to determine the scenario reserve, as discussed in Section 3.D, for each scenario.
3. The fundamental characteristic of the second type of method, referred to as the “implicit method,” is that the effectiveness of the current hedging strategy on future cash flows is evaluated, in part or in whole, outside of the stochastic cash-flow model. There are multiple ways that this type of modeling can be implemented. In this case, the reduction to the stochastic reserve otherwise calculated should be commensurate with the degree of effectiveness of the hedging strategy in reducing accumulated deficiencies otherwise calculated.

4. Regardless of the methodology used by the company, the ultimate effect of the current hedging strategy (including currently held hedge positions) on the stochastic reserve needs to recognize all risks, associated costs, imperfections in the hedges and hedging mismatch tolerances associated with the hedging strategy. The risks include, but are not limited to: basis, gap, price, parameter estimation and variation in assumptions (mortality, persistency, withdrawal, annuitization, etc.). Costs include, but are not limited to: transaction, margin (opportunity costs associated with margin requirements) and administration. In addition, the reduction to the stochastic reserve attributable to the hedging strategy may need to be limited due to the uncertainty associated with the company’s ability to implement the hedging strategy in a timely and effective manner. The level of operational uncertainty varies indirectly with the amount of time that the new or revised strategy has been in effect or mock tested.

Guidance Note: No hedging strategy is perfect. A given hedging strategy may eliminate or reduce some but not all risks, transform some risks into others, introduce new risks, or have other imperfections. For example, a delta-only hedging strategy does not adequately hedge the risks measured by the “Greeks” other than delta.

5. A safe harbor approach is permitted for those companies whose modeled hedge assets comprise only linear instruments not sensitive to implied volatility. For companies with option-based hedge strategies, electing this approach would require representing the option-based portion of the strategy as a delta-rho two-Greek hedge program. The normally modeled option portfolio would be replaced with a set of linear instruments that have the same first-order Greeks as the original option portfolio.

C. Calculation of Stochastic Reserve (Reported)

1. The company shall calculate CTE70 (best efforts)—the results obtained when the CTE70 is based on incorporating the modeling of hedges (including both currently held and future hedge positions) into the stochastic cash-flow model on a best efforts basis, including all of the factors and assumptions needed to model the hedges (e.g., stochastic implied volatility). The determination of CTE70 (best efforts) may utilize either explicit or implicit modeling techniques.

2. The company shall calculate a CTE70 (adjusted) by recalculating the CTE70 assuming the company has no hedging strategy except those to hedge interest credits and hedge assets held by the company on the valuation date, therefore following the requirements of Section 4.A.4.a and 4.A.4.b.i.

3. Because most models will include at least some approximations or idealistic assumptions, CTE70 (best efforts) may overstate the impact of the hedging strategy. To compensate for potential overstatement of the impact of the hedging strategy, the value for the stochastic reserve is given by:

\[
\text{Stochastic reserve} = \text{CTE70 (best efforts)} + E \times \max\{0, \text{CTE70 (adjusted)} - \text{CTE70 (best efforts)}\}
\]
4. The company shall specify a value for $E$ (the “error factor”) in the range from 5% to 100% to reflect the company’s view of the potential error resulting from the level of sophistication of the stochastic cash-flow model and its ability to properly reflect the parameters of the hedging strategy (i.e., the Greeks being covered by the strategy), as well as the associated costs, risks and benefits. The greater the ability of the stochastic model to capture all risks and uncertainties, the lower the value of $E$. The value of $E$ may be as low as 5% only if the model used to determine the CTE70 (best efforts) effectively reflects all of the parameters used in the hedging strategy. If certain economic risks are not hedged, yet the model does not generate scenarios that sufficiently capture those risks, $E$ must be in the higher end of the range, reflecting the greater likelihood of error. Likewise, simplistic hedge cash-flow models shall assume a higher likelihood of error.

5. The company shall conduct a formal back-test, based on an analysis of at least the most recent 12 months, to assess how well the model is able to replicate the hedging strategy in a way that supports the determination of the value used for $E$.

6. Such a back-test shall involve one of the following analyses:

a. For companies that model hedge cash flows directly (“explicit method”), replace the stochastic scenarios used in calculating the CTE70 (best efforts) with a single scenario that represents the market path that actually manifested over the selected back-testing period and compare the projected hedge asset gains and losses against the actual hedge asset gains and losses – both realized and unrealized – observed over the same time period. For this calculation, the model assumptions may be replaced with parameters that reflect actual experience during the back-testing period. In order to isolate the comparison between the modeled hedge results and actual hedge results for this calculation, the projected liabilities should accurately reflect the actual liabilities throughout the back-testing period; therefore, adjustments that facilitate this accuracy (e.g. reflecting actual experience instead of model assumptions, including new business, etc.) are permissible.

To support the choice of a low value of $E$, the company should ascertain that the projected hedge asset gains and losses are within close range of 100% (e.g., 80–125%) of the actual hedge asset gains and losses. The company may also support the choice of a low value of $E$ by achieving a high R-squared (e.g., 0.80 or higher) when using a regression analysis technique.

b. For companies that model hedge cash flows implicitly by quantifying the cost and benefit of hedging using the fair value of the hedged item (an “implicit method” or “cost of reinsurance method”), calculate the delta, rho and vega coverage ratios in each month over the selected back-testing period in the following manner:

i. Determine the hedge asset gains and losses—both realized and unrealized—incurred over the month attributable to equity, interest rate, and implied volatility movements.

ii. Determine the change in the fair value of the hedged item over the month attributable to equity, interest rate, and implied volatility movements. The hedged item should be defined in a manner that reflects the proportion of risks hedged (e.g., if a company elects to hedge 50% of a contract’s market risks, it should quantify the fair value of the hedged item as 50% of the fair value of the contract).

iii. Calculate the delta coverage ratio as the ratio between (i) and (ii) attributable to equity movements.
iv. Calculate the rho coverage ratio as the ratio between (i) and (ii) attributable to interest rate movements.

v. Calculate the vega coverage ratio as the ratio between (i) and (ii) attributable to implied volatility movements.

vi. To support the company’s choice of a low value of E, the company should be able to demonstrate that the delta and rho coverage ratios are both within close range of 100% (e.g., 80–125%) consistently across the backtesting period.

vii. In addition, the company should be able to demonstrate that the vega coverage ratio is within close range of 100% in order to use the prevailing implied volatility levels as of the valuation date in quantifying the fair value of the hedged item for the purpose of calculating CTE70 (best efforts). Otherwise, the company shall quantify the fair value of the hedged item for the purpose of calculating CTE70 (best efforts) in a manner consistent with the realized volatility of the scenarios captured in the CTE (best efforts).

c. Companies that do not model hedge cash flows explicitly, but that also do not use the implicit method as outlined in Section 9.C.6.b above, shall conduct the formal back-test in a manner that allows the company to clearly illustrate the appropriateness of the selected method for reflecting the cost and benefit of hedging, as well as the value used for E.

7. A company that does not have 12 months of experience to date shall set E to a value that reflects the amount of experience available, and the degree and nature of any change to the hedge program. For a material change in strategy, with no history, E should be at least 0.50. However, E may be lower than 0.50 if some reliable experience is available and/or if the change in strategy is a refinement rather than a substantial change in strategy.

**Guidance Note:** The following examples are provided as guidance for determining the E factor when there has been a change to the hedge program:

- The error factor should be temporarily large (e.g., ≥ 50%) for substantial changes in hedge methodology (e.g., moving from a fair-value based strategy to a stop-loss strategy) where the company has not been able to provide a meaningful simulation of hedge performance based on the new strategy.

- A temporary moderate increase (e.g., 15–30%) in error factor should be used for substantial modifications to hedge programs or modeling where meaningful simulation has not been created (e.g., adding second-order hedging, such as gamma or rate convexity).

- No increase in the error factor may be used for incremental modifications to the hedge strategy (e.g., adding death benefits to a program that previously covered only living benefits, or moving from swaps to Treasury Department futures).

D. Specific Considerations and Requirements

1. As part of the process of choosing a methodology and assumptions for estimating the future effectiveness of the current hedging strategy (including currently held hedge positions) for
purposes of reducing the stochastic reserve, the company should review actual historical hedging effectiveness. The company shall evaluate the appropriateness of the assumptions on future trading, transaction costs, other elements of the model, the strategy, the mix of business and other items that are likely to result in materially adverse results. This includes an analysis of model assumptions that, when combined with the reliance on the hedging strategy, are likely to result in adverse results relative to those modeled. The parameters and assumptions shall be adjusted (based on testing contingent on the strategy used and other assumptions) to levels that fully reflect the risk based on historical ranges and foreseeable future ranges of the assumptions and parameters. If this is not possible by parameter adjustment, the model shall be modified to reflect them at either anticipated experience or adverse estimates of the parameters.

2. A discontinuous hedging strategy is a hedging strategy where the relationships between the sensitivities to equity markets and interest rates (commonly referred to as the Greeks) associated with the guaranteed contract holder options embedded in the fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets are subject to material discontinuities. This includes, but is not limited to, a hedging strategy where material hedging assets will be obtained when the fixed indexed annuity account balances reach a predetermined level in relationship to the guarantees. Any hedging strategy, including a delta hedging strategy, can be a discontinuous hedging strategy if implementation of the strategy permits material discontinuities between the sensitivities to equity markets and interest rates associated with the guaranteed contract holder options embedded in the fixed indexed annuities and other in-scope products and these same sensitivities associated with the hedging assets. Where discontinuous hedging strategies contribute materially to a reduction in the stochastic reserve, the company must evaluate the interaction of future trigger definitions and the discontinuous hedging strategy, in addition to the items mentioned in the previous paragraph. This includes an analysis of model assumptions that, when combined with the reliance on the discontinuous hedging strategy, may result in adverse results relative to those modeled.

3. A strategy that has a strong dependence on acquiring hedging assets at specific times that depend on specific values of an index or other market indicators may not be implemented as precisely as planned.

4. The combination of elements of the stochastic cash-flow model—including the initial actual market asset prices, prices for trading at future dates, transaction costs and other assumptions—should be analyzed by the company as to whether the stochastic cash-flow model permits hedging strategies that make money in some scenarios without losing a reasonable amount in some other scenarios. This includes, but is not limited to:

   a. Hedging strategies with no initial investment that never lose money in any scenario and in some scenarios make money.

   b. Hedging strategies that, with a given amount of initial money, never make less than accumulation at the one-period risk-free rates in any scenario but make more than this in one or more scenarios.

5. If the stochastic cash-flow model allows for such situations, the company should be satisfied that the results do not materially rely directly or indirectly on the use of such strategies. If the results do materially rely directly or indirectly on the use of such strategies, the strategies may not be used to reduce the stochastic reserve otherwise calculated.
6. In addition to the above, the method used to determine prices of financial instruments for trading in scenarios should be compared to actual initial market prices. In addition to comparisons to initial market prices, there should be testing of the pricing models that are used to determine subsequent prices when scenarios involve trading financial instruments. This testing should consider historical relationships. For example, if a method is used where recent volatility in the scenario is one of the determinants of prices for trading in that scenario, then that model should approximate actual historic prices in similar circumstances in history.
Section 10: Guidance and Requirements for Setting Contract Holder Behavior Prudent Estimate Assumptions

A. General

Contract holder behavior assumptions encompass actions such as lapses, withdrawals, transfers, recurring deposits, benefit utilization, option election, etc. Contract holder behavior is difficult to predict accurately, and variance in behavior assumptions can significantly affect the results. In the absence of relevant and fully credible empirical data, the company should set behavior assumptions as guided by Principle 3 in Section 1.B.

In setting behavior assumptions, the company should examine, but not be limited by, the following considerations:

1. Behavior can vary by product, market, distribution channel, index performance, interest credited (current and guaranteed rates), time/product duration, etc.
2. Options embedded in the product may affect behavior.
3. Utilization of options may be elective or non-elective in nature. Living benefits often are elective, and death benefit options are generally non-elective.
4. Elective contract holder options may be more driven by economic conditions than non-elective options.
5. As the value of a product option increases, there is an increased likelihood that contract holders will behave in a manner that maximizes their financial interest (e.g., lower lapses, higher benefit utilization, etc.).
6. Behavior formulas may have both rational and irrational components (irrational behavior is defined as situations where some contract holders may not always act in their best financial interest). The rational component should be dynamic, but the concept of rationality need not be interpreted in strict financial terms and might change over time in response to observed trends in contract holder behavior based on increased or decreased financial efficiency in exercising their contractual options.
7. Options that are ancillary to the primary product features may not be significant drivers of behavior. Whether an option is ancillary to the primary product features depends on many things, such as:
   a. For what purpose was the product purchased?
   b. Is the option elective or non-elective?
   c. Is the value of the option well-known?
8. External influences may affect behavior.

B. Aggregate vs. Individual Margins

1. Prudent estimate assumptions are developed by applying a margin for uncertainty to the anticipated experience assumption. The issue of whether the level of the margin applied to the anticipated experience assumption is determined in aggregate or independently for each and every behavior assumption is discussed in Principle 3 in Section 1.B.
2. Although this principle discusses the concept of determining the level of margins in aggregate, it notes that the application of this concept shall be guided by evolving practice and expanding knowledge. From a practical standpoint, it may not always be possible to completely apply this concept to determine the level of margins in aggregate for all behavior assumptions.

3. Therefore, the company shall determine prudent estimate assumptions independently for each behavior (e.g., mortality, lapses and benefit utilization), using the requirements and guidance in this section and throughout these requirements, unless the company can demonstrate that an appropriate method was used to determine the level of margin in aggregate for two or more behaviors.

C. Sensitivity Testing

The impact of behavior can vary by product, time period, etc. For any assumption that is not prescribed or stochastically modeled, the qualified actuary to whom responsibility for this group of contracts is assigned shall use sensitivity testing to ensure that the assumption is set at the conservative end of the plausible range. The company shall sensitivity test:

- Surrenders.
- Partial withdrawals.
- Benefit utilization.
- Other behavior assumptions if relevant to the risks in the product.

Sensitivity testing of assumptions is required and shall be more complex than, for example, base lapse assumption plus or minus X% across all contracts. A more appropriate sensitivity test in this example might be to devise parameters in a dynamic lapse formula to reflect more out-of-the-money contracts lapsing and/or more holders of in-the-money contracts persisting and eventually using the guarantee. The company should apply more caution in setting assumptions for behaviors where testing suggests that stochastic modeling results are sensitive to small changes in such assumptions. For such sensitive behaviors, the company shall use higher margins when the underlying experience is less than fully relevant and credible.

The company shall examine the results of sensitivity testing to understand the materiality of prudent estimate assumptions on the modeled reserve. The company shall update the sensitivity tests periodically as appropriate, considering the materiality of the results of the tests. The company may update the tests less frequently when the tests show less sensitivity of the modeled reserve to changes in the assumptions being tested or the experience is not changing rapidly. Providing there is no material impact on the results of the sensitivity testing, the company may perform sensitivity testing:

1. Using samples of the contracts in force rather than performing the entire valuation for each alternative assumption set.
2. Using data from prior periods.

D. Specific Considerations and Requirements

1. Within materiality considerations, the company should consider all relevant forms of contract holder behavior and persistency, including, but not limited to, the following:
a. Mortality (additional guidance and requirements regarding mortality is contained in Section 11).

b. Surrenders.

c. Partial withdrawals (systematic and elective).

d. Account transfers (switching/exchanges).

e. Resets/ratchets of the guaranteed amounts (automatic and elective).

f. Future deposits.

g. Income start date

h. Commutation of benefit (from periodic payment to lump sum)

2. It may be acceptable to ignore certain items that might otherwise be explicitly modeled in an ideal world, particularly if the inclusion of such items reduces the calculated provisions.

For example:

a. The impact of account transfers (intra-contract index “switching”) might be ignored, unless required under the terms of the contract (e.g., automatic asset re-allocation/rebalancing,) or if the contract provisions incentivize the contract holders to transfer between accounts.

b. Future deposits might be excluded from the model, unless required by the terms of the contracts under consideration and then only in such cases where future premiums can reasonably be anticipated (e.g., with respect to timing and amount).

c. For some non-elective benefits (nursing home benefits for example), a zero incidence rate after the surrender charge has ended, or the cash value has depleted, may be acceptable since use of a non-zero rate could reduce the modeled reserve.

3. However, the company should exercise caution in assuming that current behavior will be indefinitely maintained. For example, it might be appropriate to test the impact of a shifting asset mix and/or consider future deposits to the extent they can reasonably be anticipated and increase the calculated amounts.

4. Normally, the underlying model assumptions would differ according to the attributes of the contract being valued. This would typically mean that contract holder behavior and persistency may be expected to vary according to such characteristics as (this is not an exhaustive list):

a. Gender.

b. Attained age.

c. Issue age.

d. Contract duration.

e. Time to maturity.
f. Tax status.
g. Account value.
h. Interest credited (current and guaranteed).
i. Available indices.
j. Guaranteed benefit amounts.
k. Surrender charges, transfer fees or other contract charges.
l. Distribution channel.

5. Unless there is clear evidence to the contrary, behavior assumptions should be no less conservative than past experience. Margins for contract holder behavior assumptions shall assume, without relevant and credible experience or clear evidence to the contrary, that contract holders’ efficiency will increase over time.

6. In determining contract holder behavior assumptions, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience), whether or not the segment is directly written by the company. If data from a similar business segment are used, the assumption shall be adjusted to reflect differences between the two segments. Margins shall reflect the data uncertainty associated with using data from a similar but not identical business segment.

7. Where relevant and fully credible empirical data do not exist for a given contract holder behavior assumption, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is shifted towards the conservative end of the plausible range of expected experience that serves to increase the stochastic reserve. If there are no relevant data, the company shall set the contract holder behavior assumption to reflect the increased uncertainty such that the contract holder behavior assumption is at the conservative end of the range. Such adjustments shall be consistent with the definition of prudent estimate, with the principles described in Section 1.B, and with the guidance and requirements in this section.

8. Ideally, contract holder behavior would be modeled dynamically according to the simulated economic environment and/or other conditions. It is important to note, however, that contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally. These extreme assumptions may be used for modeling efficiency if the result is more conservative.

E. Dynamic Assumptions

1. Consistent with the concept of prudent estimate assumptions described earlier, the liability model should incorporate margins for uncertainty for all risk factors that are not dynamic (i.e., the non-scenario tested assumptions) and are assumed not to vary according to the financial interest of the contract holder.

2. The company should exercise care in using static assumptions when it would be more natural and reasonable to use a dynamic model or other scenario-dependent formulation for behavior. With due regard to considerations of materiality and practicality, the use of
dynamic models is encouraged, but not mandatory. Risk factors that are not scenario tested but could reasonably be expected to vary according to a stochastic process, or future states of the world (especially in response to economic drivers) may require higher margins and/or signal a need for higher margins for certain other assumptions.

3. Risk factors that are modeled dynamically should encompass the plausible range of behavior consistent with the economic scenarios and other variables in the model, including the non-scenario tested assumptions. The company shall test the sensitivity of results to understand the materiality of making alternate assumptions and follow the guidance discussed above on setting assumptions for sensitive behaviors.

F. Consistency with the CTE Level

1. All behaviors (i.e., dynamic, formulaic and non-scenario tested) should be consistent with the scenarios used in the CTE calculations (generally, the top 30% of the loss distribution). To maintain such consistency, it is not necessary to iterate (i.e., successive runs of the model) in order to determine exactly which scenario results are included in the CTE measure. Rather, in light of the products being valued, the company should be mindful of the general characteristics of those scenarios likely to represent the tail of the loss distribution and consequently use prudent estimate assumptions for behavior that are reasonable and appropriate in such scenarios. For fixed annuities, these “valuation” scenarios would typically display one or more of the following attributes:

   a. Declining and/or volatile index values, where applicable.
   b. Price gaps and/or liquidity constraints.
   c. Rapidly changing interest rates or persistently low interest rates.
   d. Volatile credit spreads.

2. The behavior assumptions should be logical and consistent both individually and in aggregate, especially in the scenarios that govern the results. In other words, the company should not set behavior assumptions in isolation, but give due consideration to other elements of the model. The interdependence of assumptions (particularly those governing customer behaviors) makes this task difficult and by definition requires professional judgment, but it is important that the model risk factors and assumptions:

   a. Remain logically and internally consistent across the scenarios tested.
   b. Represent plausible outcomes.
   c. Lead to appropriate, but not excessive, asset requirements.

4. The company should remember that the continuum of “plausibility” should not be confined or constrained to the outcomes and events exhibited by historic experience.

5. Companies should attempt to track experience for all assumptions that materially affect their risk profiles by collecting and maintaining the data required to conduct credible and meaningful studies of contract holder behavior.

G. Additional Considerations and Requirements for Assumptions Applicable to Guaranteed Living Benefits
Experience for contracts without guaranteed living benefits may be of limited use in setting a lapse assumption for contracts with in-the-money or at-the-money guaranteed living benefits. Such experience may only be used if it is appropriate (e.g., lapse experience on contracts without a living benefit may have relevance to the early durations of contracts with living benefits) and relevant to the business.

H. Policy Loans

If policy loans are applicable for the block of business, the company shall determine cash flows for each projection interval for policy loan assets by modeling existing loan balances either explicitly or by substituting assets that are a proxy for policy loans (e.g., bonds, cash, etc.) subject to the following:

1. If the company substitutes assets that are a proxy for policy loans, the company must demonstrate that such substitution:
   a. Produces reserves that are no less than those that would be produced by modeling existing loan balances explicitly.
   b. Complies with the contract holder behavior requirements stated in Section 10 above in this section.

2. If the company models policy loans explicitly, the company shall:
   a. Treat policy loan activity as an aspect of contract holder behavior and subject to the requirements above in this section.
   b. Assign loan balances either to exactly match each policy’s utilization or to reflect average utilization over a model segment or sub-segments.
   c. Model policy loan interest in a manner consistent with policy provisions and with the scenario. Include interest paid in cash as a positive policy loan cash flow in that projection interval, but do not include interest added to the loan balance as a policy loan cash flow. (The increased balance will require increased repayment cash flows in future projection intervals.)
   d. Model policy loan principal repayments, including those that occur automatically upon death or surrender. Include policy loan principal repayments as a positive policy loan cash flow, per Section 4.A.1.h.
   e. Model additional policy loan principal. Include additional policy loan principal as a negative policy loan cash flow, per Section 4.A.1.h (but do not include interest added to the loan balance as a negative policy loan cash flow).
   f. Model any investment expenses allocated to policy loans and include them either with policy loan cash flows or insurance expense cash flows.

I. Non-Guaranteed Elements

Consistent with the definition in VM-01, Non-Guaranteed Elements (NGEs) are elements within a contract that affect policy costs or values and are not guaranteed at issue. NGEs consist of elements affecting contract holder costs or values that are both established and subject to change at the discretion of the insurer.
Examples of NGEs specific to fixed annuities include but are not limited to the following: fixed credited rates, index parameters (caps, spreads, participation rates, etc.), rider fees, rider benefit features being subject to change (rollup rates, rollup period, etc.), account value charges, and dividends under participating policies or contracts.

1. Except as noted below in Section 10.J.5, the company shall include NGE in the models to project future cash flows beyond the time the company has authorized their payment or crediting.

2. The projected NGE shall reflect factors that include, but are not limited to, the following (not all of these factors will necessarily be present in all situations):
   a. The nature of contractual guarantees.
   b. The company’s past NGE practices and established NGE policies.
   c. The timing of any change in NGE relative to the date of recognition of a change in experience.
   d. The benefits and risks to the company of continuing to authorize NGE.

3. Projected NGE shall be established based on projected experience consistent with how actual NGE are determined.

4. Projected levels of NGE in the cash-flow model must be consistent with the experience assumptions used in each scenario. Contract holder behavior assumptions in the model must be consistent with the NGE assumed in the model.

5. The company may exclude any portion of an NGE that:
   a. Is not based on some aspect of the policy’s or contract’s experience.
   b. Is authorized by the board of directors and documented in the board minutes, where the documentation includes the amount of the NGE that arises from other sources.

   However, if the board has guaranteed a portion of the NGE into the future, the company must model that amount. In other words, the company cannot exclude from its model any NGE that the board has guaranteed for future years, even if it could have otherwise excluded them, based on this subsection.

6. The liability for contract holder dividends declared but not yet paid that has been established according to statutory accounting principles as of the valuation date is reported separately from the statutory reserve. The contract holder dividends that give rise to this dividend liability as of the valuation date may or may not be included in the cash-flow model at the company’s option.
   a. If the contract holder dividends that give rise to the dividend liability are not included in the cash-flow model, then no adjustment is needed to the resulting aggregate stochastic reserve.
   b. If the contract holder dividends that give rise to the dividend liability are included in the cash-flow model, then the resulting aggregate stochastic reserve should be reduced by the amount of the dividend liability.

7. All projected cash flows associated with NGEs shall reflect margins for adverse deviations and estimation error in prudent estimate assumptions.
Section 11: Guidance and Requirements for Setting Prudent Estimate Mortality Assumptions

A. Overview

1. Intent

The guidance and requirements in this section apply to setting prudent estimate mortality assumptions when determining the stochastic reserve. The intent is for prudent estimate mortality assumptions to be based on facts, circumstances and appropriate actuarial practice, with only a limited role for unsupported actuarial judgment. (Where more than one approach to appropriate actuarial practice exists, the company should select the practice that the company deems most appropriate under the circumstances.)

2. Description

Prudent estimate mortality assumptions shall be determined by first developing expected mortality curves based on either available experience or published tables. Where necessary, margins shall be applied to the experience to reflect data uncertainty. The expected mortality curves shall then be adjusted based on the credibility of the experience used to determine the expected mortality curve. Section 11.B addresses guidance and requirements for determining expected mortality curves, and Section 11.C addresses guidance and requirements for adjusting the expected mortality curves to determine prudent estimate mortality.

Finally, the credibility-adjusted tables shall be adjusted for mortality improvement (where such adjustment is permitted or required) using the guidance and requirements in Section 11.D.

3. Business Segments

For purposes of setting prudent estimate mortality assumptions, the products falling under the scope of these requirements shall be grouped into business segments with different mortality assumptions. The grouping, at a minimum, should differentiate between payout annuities or deferred annuity contracts that contain GLBs, and deferred annuity contracts with no guaranteed benefits or only GMDBs. Where appropriate, the grouping should also differentiate between segments which are known or expected to contain contract holders with sociodemographic, geographic, or health factors reasonably expected to impact the mortality assumptions for the segment (e.g., annuitants drawn from different countries, geographic areas, industry groups, or impaired lives on individually underwritten contracts such as structured settlements). The grouping should also generally follow the pricing, marketing, management and/or reinsurance programs of the company.

Guidance Note: This paragraph contemplates situations where it may be appropriate to differentiate mortality assumptions by segment or even by contract due to varying sociodemographic, geographic, or health factors. Particularly, though not exclusively, in the context of group payout annuity contracts, companies may have credible, contract-specific mortality experience data or relevant pooled data from annuitants drawn from similar industries or geographies that may be used to sub-divide inforce blocks into business segments for purposes of setting prudent estimate mortality assumptions.

For example, a company may sell group PRT contracts both to union plans in the U.S. and to private single-employer plans in another country. While both are “PRT contracts,” it would be appropriate to differentiate them for mortality assumption purposes, similar to
how payout annuities vs. deferred annuities are distinguished.

**Guidance Note:** Distinct mortality or liability assumptions among different contracts within a group of contracts does not in itself preclude the group of contracts from being aggregated for the purposes of the broader stochastic reserve calculation.

4. Margin for Data Uncertainty

The expected mortality curves that are determined in Section 11.B may need to include a margin for data uncertainty. The margin could be in the form of an increase or a decrease in mortality, depending on the business segment under consideration. The margin shall be applied in a direction (i.e., increase or decrease in mortality) that results in a higher reserve. A sensitivity test may be needed to determine the appropriate direction of the provision for uncertainty to mortality. The test could be a prior year mortality sensitivity analysis of the business segment or an examination of current representative cells of the segment.

For purposes of this section, if mortality must be increased (decreased) to provide for uncertainty, the business segment is referred to as a plus (minus) segment.

It may be necessary, because of a change in the mortality risk profile of the segment, to reclassify a business segment from a plus (minus) segment to a minus (plus) segment to the extent compliance with this section requires such a reclassification. For example, a segment could require reclassification depending on whether it is gross or net of reinsurance.

**B. Determination of Expected Mortality Curves**

1. Experience Data

In determining expected mortality curves, the company shall use actual experience data directly applicable to the business segment (i.e., direct data) if it is available. In the absence of direct data, the company should then look to use data from a segment that is similar to the business segment (i.e., other than direct experience). See Section 11.B.2. for additional considerations. Finally, if there is no data, the company shall use the applicable table, as required in Section 11.B.3.

2. Data Other Than Direct Experience

Adjustments shall be applied to the data to reflect differences between the business segments, and margins shall be applied to the adjusted expected mortality curves to reflect the data uncertainty associated with using data from a similar but not identical business segment.

To the extent the mortality of a business segment is reinsured, any mortality charges that are consistent with the company’s own pricing and applicable to a substantial portion of the mortality risk also may be a reasonable starting point for the determination of the company’s expected mortality curves.

3. No Data Requirements

   i. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no less than:
a. [2021 SOA Deferred Annuity Mortality Table] with [Projection Scale G2] for individual deferred annuities that do not contain guaranteed living benefits

\[ q_{x}^{20XX+n} = q_{x}^{20XX} (1 - G2_x)^n \]

ii. When little or no experience or information is available on a business segment, the company shall use expected mortality curves that would produce expected deaths no greater than:

a. [The appropriate percentage (Fx) from Table 11.1 applied to the 2012 IAM Basic Mortality Table] with [Projection Scale G2] for individual payout annuity contracts and deferred annuity contracts with guaranteed living benefits

\[ q_{x}^{2012+n} = q_{x}^{2012} (1 - G2_x)^n * F_x \]

b. [1983 Table “a”] for structured settlements or other contracts with impaired mortality

c. [1994 GAR Table] with [Projection Scale AA] for group annuities

\[ q_{x}^{1994+n} = d_{x}^{1994} (1 - AA_x)^n \]

</tbody>
</table>
iii. For a business segment with non-U.S. insureds, an established industry or national mortality table may be used, with approval from the domiciliary commissioner.

4. Additional Considerations Involving Data

The following considerations shall apply to mortality data specific to the business segment for which assumptions are being determined (i.e., direct data discussed in Section 11.B.1 or other than direct data discussed in Section 11.B.2).

a. Underreporting of Deaths

Mortality data shall be examined for possible underreporting of deaths. Adjustments shall be made to the data if there is any evidence of underreporting. Alternatively, exposure by lives or amounts on contracts for which death benefits were in the money may be used to determine expected mortality curves. Underreporting on such exposures should be minimal; however, this reduced subset of data will have less credibility.

b. Experience by Contract Duration

Experience of a plus segment shall be examined to determine if mortality by contract duration increases materially due to selection at issue. In the absence of information, the company shall assume that expected mortality will increase by contract duration for an appropriate select period. As an alternative, if the company determines that mortality is affected by selection, the company could apply margins to the expected mortality in such a way that the actual mortality modeled does not depend on contract duration.

c. Modification and Relevance of Data
Even for a large company, the quantity of life exposures and deaths are such that a significant amount of smoothing may be required to determine expected mortality curves from mortality experience. Expected mortality curves, when applied to the recent historic exposures (e.g., three to seven years), should not result in an estimate of aggregate number of deaths less (greater) than the actual number deaths during the exposure period for plus (minus) segments.

In determining expected mortality curves (and the credibility of the underlying data), older data may no longer be relevant. The “age” of the experience data used to determine expected mortality curves should be documented.

d. Other Considerations

In determining expected mortality curves, consideration should be given to factors that include, but are not limited to, trends in mortality experience, trends in exposure, volatility in year-to-year A/E mortality ratios, mortality by lives relative to mortality by amounts, changes in the mix of business and product features that could lead to mortality selection.

C. Adjustment for Credibility to Determine Prudent Estimate Mortality

1. Adjustment for Credibility

The expected mortality curves determined in Section 11.B shall be adjusted based on the credibility of the experience used to determine the curves in order to arrive at prudent estimate mortality. The adjustment for credibility shall result in blending the expected mortality curves with the mortality assumption described in Section 11.B.3. The approach used to adjust the curves shall suitably account for credibility.

**Guidance Note:** For example, when credibility is zero, an appropriate approach should result in a mortality assumption consistent with 100% of the mortality table used in the blending.

2. Adjustment of Statutory Valuation Mortality for Improvement

For purposes of the adjustment for credibility, the mortality table for a plus segment may be and the mortality table for a minus segment must be adjusted for mortality improvement. Such adjustment shall reflect the mortality improvement scale described in Section 11.B.3 from the effective date of the respective mortality table to the experience weighted average date underlying the data used to develop the expected mortality curves.

3. Credibility Procedure

The credibility procedure used shall:

a. Produce results that are reasonable.

b. Not tend to bias the results in any material way.

c. Be practical to implement.

d. Give consideration to the need to balance responsiveness and stability.

e. Take into account not only the level of aggregate claims but the shape of the mortality curve.
f. Contain criteria for full credibility and partial credibility that have a sound statistical basis and be appropriately applied.

4. Further Adjustment of the Credibility-Adjusted Table for Mortality Improvement

The credibility-adjusted table used for plus segments may be and the credibility adjusted table used for minus segments must be adjusted for mortality improvement using the applicable mortality improvement scale described in Section 11.B.3 from the experience weighted average date underlying the company experience used in the credibility process to the valuation date.

Any adjustment for mortality improvement beyond the valuation date is discussed in Section 11.D.

D. Future Mortality Improvement

The mortality assumption resulting from the requirements of Section 11.C shall be adjusted for mortality improvements beyond the valuation date if such an adjustment would serve to increase the resulting stochastic reserve. If such an adjustment would reduce the stochastic reserve, such assumptions are permitted, but not required. In either case, the assumption must be based on current relevant data with a margin for uncertainty (increasing assumed rates of improvement if that results in a higher reserve or reducing them otherwise).
Section 12: Allocation of Aggregate Reserves to the Contract Level

Section 3.F states that the aggregate reserve shall be allocated to the contracts falling within the scope of these requirements. That allocation should be done for both the pre- and post-reinsurance ceded reserves. Contracts that have passed the stochastic exclusion test as defined in Section 7.B will not be included in the allocation of the aggregate reserve. For the purpose of this section, if a contract does not have a cash surrender value, then the cash surrender value is assumed to be zero.

Contracts for which the Deterministic Certification Option is elected in Section 7.E are intended to use the methodology described in this section to allocate aggregate reserves in excess of the cash surrender value to individual contracts.

The contract-level reserve for each contract shall be the sum of the following:

A. The contract’s cash surrender value.

Drafting Note: The American Academy of Actuaries Annuity Reserves and Capital Work Group is including two potential options for allocating the excess portion of the aggregate reserve over cash surrender value: (1) Use the same approach as VM-21 (2) Allocate based on an actuarial present value calculation.

The Work Group did not reach a consensus between these two approaches, so wording for both is included in the text below. The Work Group recommends field testing both approaches and considering the results in determining future decisions.

Option 1: VM-21 Approach

B. An allocated portion of the excess of the aggregate reserve over the aggregate cash surrender value shall be allocated to each contract based on a measure of the risk of that product relative to its cash surrender value in the context of the company’s in force contracts (assuming zero cash value for contracts that do not contain such). The measure of risk should consider the impact of risk mitigation programs, including hedge programs and reinsurance, that would affect the risk of the product. The specific method of assessing that risk and how it contributes to the company’s aggregate reserve shall be defined by the company. The method should provide for an equitable allocation based on risk analysis.

1. As an example, consider a company with the results of the following three contracts:

Table 12.1: Sample Allocation of Aggregate Reserve

<table>
<thead>
<tr>
<th>Contract (i)</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cash Surrender Value, C</td>
<td>28</td>
<td>40</td>
<td>52</td>
<td>120</td>
</tr>
<tr>
<td>Risk adjusted measure, R</td>
<td>38</td>
<td>52</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>Aggregate Reserve</td>
<td></td>
<td></td>
<td></td>
<td>140</td>
</tr>
<tr>
<td>Allocation Basis for the excess of the Aggregate Reserve over the Cash Surrender Value</td>
<td>10</td>
<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>

Ai = Max(Ri-Ci, 0)
2. In this example, the Aggregate Reserve exceeds the aggregate Cash Surrender Value by 20. The 20 is allocated proportionally across the three contracts based on the allocation basis of the larger of (i) zero; and (ii) a risk adjusted measure based on reserve principles. Therefore, contracts 1 and 2 receive 45% (9/22) and 55% (11/22), respectively, of the excess Aggregate Reserve. As Contract 3 presents no risk in excess of its cash surrender value, it does not receive an allocation of the excess Aggregate Reserve.

Option 2: Actuarial Present Value Approach

B. The excess of the aggregate reserve over the aggregate cash surrender value is allocated to policies based on a calculation of the actuarial present value of projected liability cash flows in excess of the cash surrender value:

1. Discount the liability cash flows at the NAER, pursuant to requirements in Section 4, for the scenario that produces the scenario reserve closest to, but not less than the stochastic reserve defined in Section 3.D.

   a. Groups of contracts that elect the Deterministic Certification Option defined in Section 7.E shall use the NAER in the single scenario used to calculate the reserve to discount liability cash flows.

2. If the actuarial present value is less than the cash surrender value, then the excess actuarial present value to be used for allocating the excess aggregate reserve over the cash value shall be floored at zero.

   a. If all contracts have an excess actuarial present value that is floored at zero, then use the cash surrender value to allocate any excess aggregate reserve over the aggregate cash surrender value.

3. For projecting future liability cash flows, assume the same liability assumptions that were used to calculate the stochastic reserve defined in 3.D.

4. As a hypothetical example, consider a company with the results of the following five contracts:

<table>
<thead>
<tr>
<th>Allocation of the excess of the Aggregate Reserve over the Cash Surrender Value</th>
<th>9.09</th>
<th>10.91</th>
<th>0.00</th>

*Cash Surrender Value  
**Guaranteed Lifetime Withdrawal Benefit

**Guidance Note:** The actuarial present value (APV) in the section above is separate from the Guarantee Actuarial Present Value (GAPV) referred to in the additional standard projection amount calculation in VM-21. The GAPV is only applicable to guaranteed minimum benefits and uses prescribed liability assumptions. In contrast, the APV in this section applies to the entire contract, irrespective of whether guaranteed benefits are attached, and uses company prudent estimate liability assumptions.
Section 13: Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves

A. Purpose and Scope

1. These requirements define for single premium immediate annuity contracts and other similar contracts, certificates and contract features the statutory maximum valuation interest rate that complies with Model #820. These are the maximum interest rate assumption requirements to be used in the CARVM and for certain contracts, the CRVM. These requirements do not preclude the use of a lower valuation interest rate assumption by the company if such assumption produces statutory reserves at least as great as those calculated using the maximum rate defined herein.

2. The following categories of contracts, certificates and contract features, whether group or individual, including both life contingent and term certain only contracts, directly written or assumed through reinsurance, with the exception of benefits arising from variable annuities, are covered in this section:

   a. Immediate annuity contracts issued after Dec. 31, 2017;
   b. Deferred income annuity contracts issued after Dec. 31, 2017;
   c. Structured settlements in payout or deferred status issued after Dec. 31, 2017;
   d. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued after Dec. 31, 2017;
   e. Fixed payout annuities resulting from the exercise of settlement options or annuitizations of host contracts issued during 2017, for fixed payouts commencing after Dec. 31, 2018, or, at the option of the company, for fixed payouts commencing after Dec. 31, 2017;
   f. Supplementary contracts, excluding contracts with no scheduled payments (such as retained asset accounts and settlements at interest), issued after Dec. 31, 2017;
   g. Fixed income payment streams, attributable to contingent deferred annuities (CDAs) issued after Dec. 31, 2017, once the underlying contract funds are exhausted;
   h. Fixed income payment streams attributable to guaranteed living benefits associated with deferred annuity contracts issued after Dec. 31, 2017, once the contract funds are exhausted; and
   i. Certificates with premium determination dates after Dec. 31, 2017, emanating from non-variable group annuity contracts specified in Model #820, Section 5.C.2, purchased for the purpose of providing certificate holders benefits upon their retirement.

   [Guidance Note: For Section 13.A.2.d, Section 13.A.2.e, Section 13.A.2.f and Section 13.A.2.h above, there is no restriction on the type of contract that may give rise to the benefit.]

3. Exemptions:

   a. With the permission of the domiciliary commissioner, for the categories of annuity contracts, certificates and/or contract features in scope as outlined in Section 13.A.2.d, Section 13.A.2.e, Section 13.A.2.f, Section 13.A.2.g or Section 13.A.2.h, the company may use the same maximum valuation interest rate used to value the payment stream in accordance with the guidance applicable to the host contract. In order to obtain such
permission, the company must demonstrate that its investment policy and practices are consistent with this approach.

4. The maximum valuation interest rates for the contracts, certificates and contract features within the scope of Section 13 of VM-22 supersede those described in Appendix VM-A and Appendix VM-C, but they do not otherwise change how those appendices are to be interpreted. In particular, Actuarial Guideline IX-B—Clarification of Methods Under Standard Valuation Law for Individual Single Premium Immediate Annuities, Any Deferred Payments Associated Therewith, Some Deferred Annuities and Structured Settlements Contracts (AG-9-B) (see VM-C) provides guidance on valuation interest rates and is, therefore, superseded by these requirements for contracts, certificates and contract features in scope. Likewise, any valuation interest rate references in Actuarial Guideline IX-C—Use of Substandard Annuity Mortality Tables in Valuing Impaired Lives Under Individual Single Premium Immediate Annuities (AG-9-C) (see VM-C) are also superseded by these requirements.

B. Definitions

1. The term “reference period” means the length of time used in assigning the Valuation Rate Bucket for the purpose of determining the statutory maximum valuation interest rate and is determined as follows:
   a. For contracts, certificates or contract features with life contingencies and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the earlier of: i) the date of the last non-life-contingent payment under the contract, certificate or contract feature; and ii) the date of the first life-contingent payment under the contract, certificate or contract feature, or
   b. For contracts, certificates or contract features with no life-contingent payments and substantially similar payments, the reference period is the length of time, rounded to the nearest year, from the premium determination date to the date of the last non-life-contingent payment under the contract, certificate or contract feature, or
   c. For contracts, certificates or contract features where the payments are not substantially similar, the actuary should apply prudent judgment and select the Valuation Rate Bucket with Macaulay duration that is a best fit to the Macaulay duration of the payments in question.

   **Guidance Note:** Contracts with installment refunds or similar features should consider the length of the installment period calculated from the premium determination date as the non-life contingent period for the purpose of determining the reference period.

   **Guidance Note:** The determination in Section 13.B.1.c above shall be made based on the materiality of the payments that are not substantially similar relative to the life-contingent payments.

2. The term “jumbo contract” means a contract with an initial consideration equal to or greater than $250 million. Considerations for contracts issued by an insurer to the same contract holder within 90 days shall be combined for purposes of determining whether the contracts meet this threshold.

   **Guidance Note:** If multiple contracts meet this criterion in aggregate, then each contract is a jumbo contract.

3. The term “non-jumbo contract” means a contract that does not meet the definition of a jumbo contract.
4. The term “premium determination date” means the date as of which the valuation interest rate for the contract, certificate or contract feature being valued is determined.

5. The term “initial age” means the age of the annuitant as of his or her age last birthday relative to the premium determination date. For joint life contracts, certificates or contract features, the “initial age” means the initial age of the younger annuitant. If a contract, certificate or contract feature for an annuitant is being valued on a standard mortality table as an impaired annuitant, “initial age” means the rated age. If a contract, certificate or contract feature is being valued on a substandard mortality basis, “initial age” means an equivalent rated age.

6. The term “Table X spreads” means the prescribed VM-22 Section 13 current market benchmark spreads for the quarter prior to the premium determination date, as published on the Industry tab of the NAIC website. The process used to determine Table X spreads is the same as that specified in VM-20 Appendix 2.D for Table F, except that JP Morgan and Bank of America bond spreads are averaged over the quarter rather than the last business day of the month.

7. The term “expected default cost” means a vector of annual default costs by weighted average life. This is calculated as a weighted average of the VM-20 Table A prescribed annual default costs published on the Industry tab of the NAIC website in effect for the quarter prior to the premium determination date, using the prescribed portfolio credit quality distribution as weights.

8. The term “expected spread” means a vector of spreads by weighted average life. This is calculated as a weighted average of the Table X spreads, using the prescribed portfolio credit quality distribution as weights.

9. The term “prescribed portfolio credit quality distribution” means the following credit rating distribution:
   a. 5% Treasuries
   b. 15% Aa bonds (5% Aa1, 5% Aa2, 5% Aa3)
   c. 40% A bonds (13.33% A1, 13.33% A2, 13.33% A3)*
   d. 40% Baa bonds (13.33% Baa1, 13.33% Baa2, 13.33% Baa3)*

   *40%/3 is used unrounded in the calculations.

C. Determination of the Statutory Maximum Valuation Interest Rate

1. Valuation Rate Buckets
   a. For the purpose of determining the statutory maximum valuation interest rate, the contract, certificate or contract feature being valued must be assigned to one of four Valuation Rate Buckets labeled A through D.
   b. If the contract, certificate or contract feature has no life contingencies, the Valuation Rate Bucket is assigned based on the length of the reference period (RP), as follows:
c. If the contract, certificate or contract feature has life contingencies, the Valuation Rate Bucket is assigned based on the length of the RP and the initial age of the annuitant, as follows:

Table 3-2: Assignment to Valuation Rate Bucket by Reference Period and Initial Age

<table>
<thead>
<tr>
<th>Initial Age</th>
<th>RP ≤ 5Y</th>
<th>5Y &lt; RP ≤ 10Y</th>
<th>10Y &lt; RP ≤ 15Y</th>
<th>RP &gt; 15Y</th>

2. Premium Determination Dates

a. The following table specifies the decision rules for setting the premium determination date for each of the contracts, certificates and contract features listed in Section 1:

Table 3-3: Premium Determination Dates

<table>
<thead>
<tr>
<th>Section</th>
<th>Item Description</th>
<th>Premium determination date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.2.a</td>
<td>Immediate annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.b</td>
<td>Deferred income annuity</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.c</td>
<td>Structured settlements</td>
<td>Date consideration is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.d and A.2.e</td>
<td>Fixed payout annuities resulting from settlement options or annuitizations from host contracts</td>
<td>Date consideration for benefit is determined and committed to by contract holder</td>
</tr>
<tr>
<td>A.2.f</td>
<td>Supplementary contracts</td>
<td>Date of issue of supplementary contract</td>
</tr>
<tr>

</tr>
<tr>
<td>A.2.h</td>
<td>Fixed income payment streams from guaranteed living benefits, AV becomes 0</td>
<td>Date on which AV becomes 0</td>
</tr>
</tbody>
</table>
Guidance Note: For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

### Guidance Note

<table>
<thead>
<tr>
<th>A.2.i</th>
<th>Group annuity and related certificates</th>
<th>Date consideration is determined and committed to by contract holder</th>
</tr>
</thead>
</table>

#### Guidance Note

For the purposes of the items in the table above, the phrase “date consideration is determined and committed to by the contract holder” should be interpreted by the company in a manner that is consistent with its standard practices. For some products, that interpretation may be the issue date or the date the premium is paid.

**b. Immaterial Change in Consideration**

If the premium determination date is based on the consideration, and if the consideration changes by an immaterial amount (defined as a change in present value of less than 10% and less than $1 million) subsequent to the original premium determination date, such as due to a data correction, then the original premium determination date shall be retained. In the case of a group annuity contract where a single premium is intended to cover multiple certificates, certificates added to the contract after the premium determination date that do not trigger the company’s right to reprice the contract shall be treated as if they were included in the contract as of the premium determination date.

### 3. Statutory Maximum Valuation Interest Rate

**a. For a given contract, certificate or contract feature, the statutory maximum valuation interest rate is determined based on its assigned Valuation Rate Bucket (Section 13.C.1) and its Premium Determination Date (Section 13.C.2) and whether the contract associated with it is a jumbo contract or a non-jumbo contract.**

**b. Statutory maximum valuation interest rates for jumbo contracts are determined and published daily by the NAIC on the Industry tab of the NAIC website. For a given premium determination date, the statutory maximum valuation interest rate is the daily statutory maximum valuation interest rate published for that premium determination date.**

**c. Statutory maximum valuation interest rates for non-jumbo contracts are determined and published quarterly by the NAIC on the Industry tab of the NAIC website by the third business day of the quarter. For a given premium determination date, the statutory maximum valuation interest rate is the quarterly statutory maximum valuation interest rate published for the quarter in which the premium determination date falls.**

**d. Quarterly Valuation Rate:**

For each Valuation Rate Bucket, the quarterly valuation rate is defined as follows:

\[ I_q = R + S - D - E \]

Where:

a. R is the reference rate for that Valuation Rate Bucket (defined in Section 13.C.4);

b. S is the spread rate for that Valuation Rate Bucket (defined in Section 13.C.5);

c. D is the default cost rate for that Valuation Rate Bucket (defined in Section 13.C.6);
and

d. E is the spread deduction defined as 0.25%.

e. Daily Valuation Rate:

For each Valuation Rate Bucket, the daily valuation rate is defined as follows:

\[ I_d = I_q + C_{d-1} - C_q \]

Where:

a. \( I_q \) is the quarterly valuation rate for the calendar quarter preceding the business day immediately preceding the premium determination date;

b. \( C_{d-1} \) is the daily corporate rate (defined in Section 13.C.7) for the business day immediately preceding the premium determination date; and

c. \( C_q \) is the average daily corporate rate (defined in Section 13.C.8) corresponding to the same period used to develop \( I_q \).

For jumbo contracts, the daily statutory maximum valuation interest rate is the daily valuation rate \( (I_d) \) rounded to the nearest one-hundredth of one percent (1/100 of 1%).

4. Reference Rate

Reference rates are updated quarterly as described below:

a. The “quarterly Treasury rate” is the average of the daily Treasury rates for a given maturity over the calendar quarter prior to the premium determination date. The quarterly Treasury rate is downloaded from https://fred.stlouisfed.org, and is rounded to two decimal places.

b. Download the quarterly Treasury rates for two-year, five-year, 10-year and 30-year U.S. Treasuries.

c. The reference rate for each Valuation Rate Bucket is calculated as the weighted average of the quarterly Treasury rates using Table 1 weights (defined in Section 13.C.9) effective for the calendar year in which the premium determination date falls.

5. Spread

The spreads for each Valuation Rate Bucket are updated quarterly as described below:

a. Use the Table X spreads from the NAIC website for WALs two, five, 10 and 30 years only to calculate the expected spread.

b. Calculate the spread for each Valuation Rate Bucket, which is a weighted average of the expected spreads for WALs two, five, 10 and 30 using Table 2 weights (defined in Section 3.I) effective for the calendar year in which the premium determination date falls.

6. Default costs for each Valuation Rate Bucket are updated annually as described below:

a. Use the VM-20 prescribed annual default cost table (Table A) in effect for the quarter prior to the premium determination date for WAL two, WAL five and WAL 10 years only to calculate the expected default cost. Table A is updated and published annually on
the Industry tab of the NAIC website during the second calendar quarter and is used for premium determination dates starting in the third calendar quarter.

b. Calculate the default cost for each Valuation Rate Bucket, which is a weighted average of the expected default costs for WAL two, WAL five and WAL 10, using Table 3 weights (defined in Section 13.C.9) effective for the calendar year in which the premium determination date falls.

7. Daily Corporate Rate

Daily corporate rates for each valuation rate bucket are updated daily as described below:

a. Each day, download the Bank of America Merrill Lynch U.S. corporate effective yields as of the previous business day’s close for each index series shown in the sample below from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from the table below].

<table>
<thead>
<tr>
<th>Maturity</th>
<th>Series Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1Y – 3Y</td>
<td>BAMLC1A0C13YEY</td>
</tr>
<tr>
<td>3Y – 5Y</td>
<td>BAMLC2A0C35YEY</td>
</tr>
<tr>
<td>5Y – 7Y</td>
<td>BAMLC3A0C57YEY</td>
</tr>
<tr>
<td>7Y – 10Y</td>
<td>BAMLC4A0C710YEY</td>
</tr>
<tr>
<td>10Y – 15Y</td>
<td>BAMLC7A0C1015YEY</td>
</tr>
<tr>
<td>15Y+</td>
<td>BAMLC8A0C15PYEY</td>
</tr>
</tbody>
</table>

b. Calculate the daily corporate rate for each valuation rate bucket, which is a weighted average of the Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 13.C.9) effective for the calendar year in which the business date immediately preceding the premium determination date falls.

8. Average Daily Corporate Rate

Average daily corporate rates are updated quarterly as described below:

a. Download the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields for each index series shown in Section 3.G.1 from the St. Louis Federal Reserve website: https://research.stlouisfed.org/fred2/categories/32348. To access a specific series, search the St. Louis Federal Reserve website for the series name by inputting the name into the search box in the upper right corner, or input the following web address: https://research.stlouisfed.org/fred2/series/[replace with series name from Section 13.C.7.a].
b. Calculate the average daily corporate rate for each valuation rate bucket, which is a weighted average of the quarterly average Bank of America Merrill Lynch U.S. corporate effective yields, using Table 4 weights (defined in Section 13.C.9) for the same calendar year as the weight tables (i.e. Tables 1, 2, and 3) used in calculating \( I_\text{q} \) in Section 13.C.3.e.

9. Weight Tables 1 through 4

The system for calculating the statutory maximum valuation interest rates relies on a set of four tables of weights that are based on duration and asset/liability cash-flow matching analysis for representative annuities within each valuation rate bucket. A given set of weight tables is applicable to the calculations for every day of the calendar year.

In the fourth quarter of each calendar year, the weights used within each valuation rate bucket for determining the applicable valuation interest rates for the following calendar year will be updated using the process described below. In each of the four tables of weights, the weights in a given row (valuation rate bucket) must add to exactly 100%.

**Weight Table 1**

The process for determining Table 1 weights is described below:

a. Each valuation rate bucket has a set of representative annuity forms. These annuity forms are as follows:

i. Bucket A:
   a) Single Life Annuity age 91 with 0 and five-year certain periods.
   b) Five-year certain only.

ii. Bucket B:
   a) Single Life Annuity age 80 and 85 with 0, five-year and 10-year certain periods.
   b) 10-year certain only.

iii. Bucket C:
   a) Single Life Annuity age 70 with 0 and 15-year certain periods.
   b) Single Life Annuity age 75 with 0, 10-year and 15-year certain periods.
   c) 15-year certain only.

iv. Bucket D:
   a) Single Life Annuity age 55, 60 and 65 with 0 and 15-year certain periods.
   b) 25-year certain only.

b. Annual cash flows are projected assuming annuity payments are made at the end of each year. These cash flows are averaged for each valuation rate bucket across the annuity forms for that bucket using the statutory valuation mortality table in effect for the following calendar year for individual annuities for males (ANB).
c. The average daily rates in the third quarter for the two-year, five-year, 10-year and 30-year U.S. Treasuries are downloaded from https://fred.stlouisfed.org as input to calculate the present values in Step d.

d. The average cash flows are summed into four time period groups: years 1–3, years 4–7, years 8–15 and years 16–30. (Note: The present value of cash flows beyond year 30 are discounted to the end of year 30 and included in the years 16–30 group. This present value is based on the lower of 3% and the 30-year Treasury rate input in Step c.)

e. The present value of each summed cash-flow group in Step d is then calculated by using the Step 3 U.S. Treasury rates for the midpoint of that group (and using the linearly interpolated U.S. Treasury rate when necessary).

f. The duration-weighted present value of the cash flows is determined by multiplying the present value of the cash-flow groups by the midpoint of the time period for each applicable group.

g. Weightings for each cash-flow time period group within a valuation rate bucket are calculated by dividing the duration weighted present value of the cash flow by the sum of the duration weighted present value of cash flow for each valuation rate bucket.

Weight Tables 2 through 4

Weight Tables 2 through 4 are determined using the following process:

i. Table 2 is identical to Table 1.

ii. Table 3 is based on the same set of underlying weights as Table 1, but the 10-year and 30-year columns are combined since VM-20 default rates are only published for maturities of up to 10 years.

iii. Table 4 is derived from Table 1 as follows:

a) Column 1 of Table 4 is identical to column 1 of Table 1.
b) Column 2 of Table 4 is 50% of column 2 of Table 1.
c) Column 3 of Table 4 is identical to column 2 of Table 4.
d) Column 4 of Table 4 is 50% of column 3 of Table 1.
e) Column 5 of Table 4 is identical to column 4 of Table 4.
f) Column 6 of Table 4 is identical to column 4 of Table 1.

10. Group Annuity Contracts

For a group annuity purchased under a retirement or deferred compensation plan (Section 13.A.2.i), the following apply:

a. The statutory maximum valuation interest rate shall be determined separately for each certificate, considering its premium determination date, the certificate holder’s initial age, the reference period corresponding to its form of payout and whether the contract is a jumbo contract or a non-jumbo contract.

Guidance Note: Under some group annuity contracts, certificates may be purchased on different dates.
b. In the case of a certificate whose form of payout has not been elected by the beneficiary at its premium determination date, the statutory maximum valuation interest rate shall be based on the reference period corresponding to the normal form of payout as defined in the contract or as is evidenced by the underlying pension plan documents or census file. If the normal form of payout cannot be determined, the maximum valuation interest rate shall be based on the reference period corresponding to the annuity form available to the certificate holder that produces the most conservative rate.

**Guidance Note:** The statutory maximum valuation interest rate will not change when the form of payout is elected.

Valuation Manual Section II. Reserve Requirements

Subsection 2: Annuity Products

A. This subsection establishes reserve requirements for all contracts classified as annuity contracts as defined in SSAP No. 50 in the AP&P Manual.

B. Minimum reserve requirements for variable annuity (VA) contracts and similar business, specified in VM-21, Requirements for Principle-Based Reserves for Variable Annuities, shall be those provided by VM-21. The minimum reserve requirements of VM-21 are considered PBR requirements for purposes of the Valuation Manual.

C. Minimum reserve requirements for fixed annuity contracts issued prior to 1/1/2024 are those requirements as found in VM-A and VM-C as applicable, with the exception of the minimum requirements for the valuation interest rate for single premium immediate annuity contracts, and other similar contracts, issued after Dec. 31, 2017, including those fixed payout annuities emanating from host contracts issued on or after Jan. 1, 2017, and on or before Dec. 31, 2017. The maximum valuation interest rate requirements for those contracts and fixed payout annuities are defined in Section 13 of VM-22, Statutory Maximum Valuation Interest Rates for Income Annuity Formulaic Reserves.

D. Minimum reserve requirements for fixed annuity contracts issued on 1/1/2024 and later are those requirements as found in Sections 1 through 12 of VM-22.

E. The below principles may serve as key considerations for assessing whether VM-21 or VM-22 requirements apply:

1. Index-linked or modified guaranteed annuity contracts or riders that satisfy both of the following conditions may be a key consideration for application of VM-22 requirements:
   a. Guarantees the principal amount of purchase payments, net of any partial withdrawals, and interest credited thereto, less any deduction (without regard to its timing) for sales, administrative or other expenses or charges.
   b. Credits a rate of interest under the contract that is at least equal to the minimum rate required to be credited by the standard nonforfeiture law in the jurisdiction in which the contract is issued.

   Guidance Note: Paragraph E.1.b is intended to apply prior to the application of any market value adjustments for modified guaranteed annuities where the underlying assets are held in a separate account. If meeting Paragraph E.1.b prior to the application of any market value adjustments and Paragraph E.1.a above, it may be appropriate to value such contracts under VM-22 requirements.

2. Index-linked or modified guaranteed annuity contracts that do not satisfy either of the two conditions listed above in Paragraph E.1.i and E.1.ii may be a key consideration for application of VM-21 requirements.
Subsection 6: Riders and Supplemental Benefits

**Guidance Note:** Policies or contracts with riders and supplemental benefits which are created to simply disguise benefits subject to the Valuation Manual section describing the reserve methodology for the base product to which they are attached, or exploit a perceived loophole, must be reserved in a manner similar to more typical designs with similar riders.

A. If a rider or supplemental benefit is attached to a health insurance product, deposit-type contract, or credit life or disability product, it may be valued with the base contract unless it is required to be separated by regulation or other requirements.

B. For supplemental benefits on life insurance policies or annuity contracts, including Guaranteed Insurability, Accidental Death or Disability Benefits, Convertibility, Nursing Home Benefits or Disability Waiver of Premium Benefits, the supplemental benefit may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A, and/or VM-C, as applicable.

C. ULSG and other secondary guarantee riders on a life insurance policy shall be valued with the base policy and follow the reserve requirements for ULSG policies under VM-20, VM-A and/or VM-C, as applicable.

D. Any guaranteed minimum benefits on life insurance policies or annuity contracts not subject to Paragraph C above including, but not limited to, Guaranteed Minimum Accumulation Benefits, Guaranteed Minimum Death Benefits, Guaranteed Minimum Income Benefits, Guaranteed Minimum Withdrawal Benefits, Guaranteed Lifetime Income Benefits, Guaranteed Lifetime Withdrawal Benefits, Guaranteed Payout Annuity Floors, Waiver of Surrender Charges, Return of Premium, Systematic Withdrawal Benefits under Required Minimum Distributions, and all similar guaranteed benefits shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

E. If a rider or supplemental benefit to a life insurance policy or annuity contract that is not addressed in Paragraphs B, C, or D above possesses any of the following attributes, the rider or supplemental benefit shall be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, and VM-A and/or VM-C, as applicable.

1. The rider or supplemental benefit does not have a separately identified premium or charge.

2. After issuance, the rider or supplemental benefit premium, charge, value or benefits are determined by referencing the base policy or contract features or performance.

3. After issuance, the base policy or contract value or benefits are determined by referencing the rider or supplemental benefit features or performance. The deduction of rider or benefit premium or charge from the contract value is not sufficient for a determination by reference.

F. If a term life insurance rider on the named insured[s] on the base life insurance policy does not meet the conditions of Paragraph E above, and either (1) guarantees level or near level premiums until a specified duration followed by a material premium increase; or (2) for a rider for which level or near level premiums are expected for a period followed by a material premium increase, the rider is separated from the base policy and follows the reserve requirements for term policies under VM20, VM-A and/or VM-C, as applicable.
G. For all other riders or supplemental benefits on life insurance policies or annuity contracts not addressed in Paragraphs B through F above, the riders or supplemental benefits may be valued with the base policy or contract and follow the reserve requirements for the base policy or contract under VM-20, VM-21, VM-22, VM-A and/or VM-C, as applicable. For a given rider, the election to include riders or supplemental benefits with the base policy or contract shall be determined at the policy form level, not on a policy-by-policy basis, and shall be treated consistently from year-to-year, unless otherwise approved by the domiciliary commissioner.

H. Any supplemental benefits and riders offered on life insurance policies or annuity contracts that would have a material impact on the reserve if elected later in the contract life, such as joint income benefits, nursing home benefits, or withdrawal provisions on annuity contracts, shall be considered when determining reserves using the following principles:

1. Policyholders with living benefits and annuitization in the same contract will generally use the more valuable of the two benefits.

2. When advantageous, policyholders will commence living benefit payouts if not started yet.

Senior Actuary  

November 19, 2021  

Mr. Bruce Sartain  
Chair, NAIC Valuation Manual (VM)-22 (A) Subgroup (Subgroup)  

Re: ACLI Comments on ARCGW VM-22 Framework Draft Proposal  

Dear Mr. Sartain:  

The American Council of Life Insurers (ACLI) appreciates the opportunity to provide comments on the American Academy of Actuaries (the Academy) Annuity Reserves and Capital Work Group VM-22 Framework Exposure.  

ACLI appreciates all the hard work of the Subgroup and ARCGW in development of this draft. We believe the framework is an excellent first step towards principles-based requirements for fixed annuities. We look forward to working with the Subgroup and ARCGW in further development of the framework, and on notable areas that were not addressed in this first exposure.  

ACLI supports the continued development of principles-based reserving. We believe that this development is the natural progression of measurement of underlying risks in company portfolios. PBR enables better measurement of complex guarantees and other risks and reflects the underlying experience of the block, while maintaining appropriate flexibility consistent with the complexity of the risks being measured.  

Our comments are broken into two sections: priority areas for requested comment and comments on individual sections of the VM-22. You will also find our comments in the accompanying Word document.  

VM-22 Exposure Comments and Priorities Comments:  

- Standard Projection Amount (SPA): If any reserve method includes a SPA, the ACLI supports making the SPA a nonbinding disclosure item across the applicable VM chapters. We appreciate the use of the SPA to help identify outlier assumptions; however, we note that having one-size-fits-all prescribed assumptions is extremely challenging due to the variety of designs in the market. Further, a binding floor introduces non-economic considerations to the reserve that do not align with management of the portfolio. Consistent with our feedback regarding the variable annuity framework, we are concerned...
about the possibility of this approach producing false positives and false negatives regarding outliers.

- Reserving Categories: We believe aggregation should be consistent with management of liabilities and assets throughout the lifecycle of the portfolio and VM-22 should allow for companies to designate aggregation of blocks consistent with their operational and investment management. Multiple categories and other aggregation limits could create disconnects with the actual management and asset portfolio of the company. Further, a greater level of aggregation encourages well-diversified portfolios and sound-risk management.

Were multiple reserve categories to be defined, we would support a principles-based categorization to accommodating innovation in the market. Further, we suggest an “at issue” approach to better align with management of the block and to avoid any disconnects in the level of the reserve were a block to switch between categories. Additionally, certain additional disclosures may not be applicable under this approach, such as those related to investment strategy when the company is not modeling it; we would suggest limiting the disclosures and reporting to items actually used in the calculation. For Option 1, we suggest deleting item #6 to be consistent with VM-21 or at least need to exclude payment streams from VAs which are scoped into VM-21.

- Model Segments (Section 3.E): Consistent with our comments on reserving categories, we believe the model segments should appropriately align with the internal management framework of companies to appropriately reflect inherent offsets in risks, which is in the spirit of a principle-based framework. We do not believe restrictive requirements around segments serves to solve any known problems, as two disjoint scenarios cannot occur at the same time within a company’s portfolio. We suggest consistency of this text with the existing VM-20 Section 7.A.1.b.

- Allocation (Section 12): We believe discussion of allocation of aggregate reserves should be analyzed as part of the field study.

- VM-21 vs. VM-22 Distinction (VM Section II edits): Consistent with the exposed framework, we support the continued inclusion of RILA and RILA-like products within VM-21. We are appreciative of the key considerations outlined in Valuation Manual Section II. Reserve Requirements Subsection 2.E and support further clarification of the intent of this text for greater clarity on the applicable guidance.

- Exclusion Test: ACLI is supportive of the exclusion test, however, we believe there are areas that could be clarified. We think there could be greater clarity regarding how exactly the exclusion test should be executed. For the Deterministic Certification Option, we request the text to be clarified regarding what business can use this option due to potential confusion in the current text; it would be clearer if the Guidance Note after 7.E.2 were moved to the beginning of Section 7.E to clarify what type of business falls into this category.
We do not believe in the necessity of including longevity risk within the scope of the exclusion test since we are not attempting to model longevity/mortality stochastically. We recommend striking longevity risk related components of this section throughout, including in 7.B and 7.C.1, and deleting the Drafting Note after 7.E.1.d.

Please find additional comments below in Section 7.

Specific feedback on sections:

- **Section 1**
  - A (Purpose): The proposal suggests VM-22 is not operative until 1/1/2024, which contradicts Section 13 and existing requirements. We would suggest rewording this to clarify that Section 13 is effective after 12/31/2017. Further, we would suggest consistency in labeling of dates (either all text or all numeric).
  - A (Relationship to RBC Requirements): The VM-21 guidance note was not included in VM-22; however, we believe it would be appropriate to retain and reword to say, “products that calculate a stochastic reserve”, since the relationship to RBC would likely be maintained.
  - B (Principles): We would support consistent application of principles across all chapters as currently VM-20 does not have a like-set of principles. We believe this could involve a broader discussion of the assorted product requirements in the VM. As a shorter-term fix, we would recommend generalizing the principles where appropriate and moving these to “Section I. Introduction” or “VM-01” and equally applying to VM-20.
  - B (Principle 2): We support this principle but note that later sections appear to contradict this principle. For example, the statement “The analysis reflects prudent estimate assumptions for deterministic variables and is performed in aggregate (subject to limitations related to contractual provisions) to allow the natural offset of risks within a given scenario.” contradicts with the introduction of additional reserve categories and other limitations (such as model segment restrictions).
  - B (Principle 3): We suggest deleting the sentence “Generally, assumptions are…” since it does not provide guidance. We also suggest tightening the remainder of the text for clarity.
  - B (Principle 5): We recommend deleting the third sentence (starting with “Therefore, the use of assumptions…”) because this lacks historical context and is covered by the final sentence.
  - C (Risks Reflected): Consistent with our comments on 1.B, we would support consistent application of risks reflected across all chapters, rather than embedding the language in each chapter. Were this to be retained in VM-22, we would suggest maintaining consistency with VM-21 to avoid any confusion.
  - C.2.c.i: We recommend removing the bullet “Risks modeled in the company’s risk assessment processes that are related to the contracts, as described above” as this is unclear and probably extraneous.
  - C.3: We recommend removing this section. With the specific RBC language removed, the section loses meaning: “a” is unnecessary and “b” is redundant with
other sections of the VM which allow for materiality considerations (language in VM-20 is likely better for this purpose and should be used consistently).

- C.4.b.iv: We recommend removing the bullet “Significant future reserve increases as an unfavorable scenario is realized” as this is extraneous.
- C.4.c (General business risks): List could be expanded to included operational risk and litigation risk.
- D (Specific definitions for VM-22): It seems the definitions included in this section are largely only used for the purpose of establishing the Scope in Section 2. Since this is intended to be a principles-based methodology, recommend a strong definition of “Fixed Annuity” instead of specific products underneath this business. The first paragraph in A. Scope seems to provide this with specific references which are out of scope. If changing the scope section, we would suggest deleting the various product definitions if not used elsewhere; if these definitions are potentially applied beyond VM-22, we would suggest moving any necessary definitions to VM-01.
- D (Deferred Income Annuity (DIA) definition/Single Premium Immediate Annuity (SPIA) definition): Suggest aligning the cut off to 13 months for alignment consistent with Actuarial Guideline IX, rather than the 1 year that currently is in the VM-22 draft.
- D (Fixed Indexed Annuity (FIA) definition): Is “typically” intended to be a requirement in the definition? That is, to qualify as FIA does there need to be guaranteed principle?
- D (Index Parameter definition): We would suggest adding performance trigger to the list, along with other potential crediting methods; alternatively, the definition could specify that the crediting methods listed are examples only.
- D (Longevity Reinsurance definition): The definition states that “Agreements which are not treated as reinsurance under Statement of Statutory Accounting Principles (SSAP) No. 61R are not included in this definition”. Why is this the case and does this imply that longevity swaps are not within the scope of VM-22? Recommend adding to the out-of-scope list in "2.A. Scope" if that is the case. Clarification would also be helpful on what guidance should be used for these agreements if out of scope for VM-22. Further, we would suggest removing “typically” from the definition.
- D (Modified Guaranteed Annuity): We recommend editing the definition as follows “A type of market-value adjusted annuity contract where the underlying assets are most commonly held in an insurance company separate account...”
- D (Pension Risk Transfer (PRT) Annuity definition): Is “typically” intended to be a requirement in the definition? That is, to qualify as PRT must the insurance company have the asset risk? Consistent with the comment on Longevity Reinsurance, it would be helpful to clarify where a longevity swap contract falls within these definitions. Notably, index-based longevity swaps should be out of scope as they do not meet definition of “annuity contract” in SSAP 50. It should also be made explicit that PRT contracts can include lump sum benefits, death benefits and cash balance benefits as well.
- D (Registered Index-Linked Annuity (RILA)): It is unclear to us why RILA is defined in VM-22 when it is being used to exclude the product from VM-22 requirements.
D (Structured Settlement Contracts (SSC)): Suggest striking sentence “Adverse mortality is typically expected for these contracts.” from definition. Additionally, it is possible that there may be non-substandard settlements.

**Section 2**
- Consistent with our comment in Section 1, the language around effective date should be clear this only applies to new PBR methodology, and rates in Section 13 have a different effective date.
- We would support reworking this section to rely on principles, rather than definitions to determine what is in and out of scope. As product innovation continues, a simple list may not appropriately accommodate the applicability of this chapter. However, if such a list is included, then we believe it should align with the full list presented in Section 13.
- We suggest moving or deleting the sentence “The company may elect to exclude one or more groups of contracts from the stochastic reserve calculation in certain situations, pursuant to the exclusion test requirements defined in Section 3.E of VM-22.” from this section as it does not seem fitting here.

**Section 3**
- B: Guidance is needed on how a pre-reinsurance reserve is to be determined.
- D: The term "Deterministic Certification Option" may be confusing, as there is no "deterministic" reserve, unlike VM-20. We recommend consideration of an alternative term. In addition, we recommend changing the phrasing to "with the exception of groups of contracts for which a company elects the [Deterministic Certification Option], following the requirements of Section 7.E."
- E.1: Seems to imply that only SPIAs would pass due to the linkage to Section 13. But the reference to interest rates should be broader, if even necessary. Suggest editing as:
  "these groups of contracts may be valued using the methodology and statutory maximum valuation rate pursuant to applicable requirements in VM-A, and VM-C, and with the statutory maximum valuation rate for immediate annuities specified in Section 13."
- E.2: This section seems to indicate that the grouping of contracts in exclusion testing should be the same as the grouping of contracts for aggregation. This might cause fewer product types to be qualifying for exclusion if the test must be performed at a higher level of aggregation.
- E (Guidance note beginning "The intention of contracts that pass the stochastic exclusion test…’"): We believe this guidance note is unnecessary as the intent of the section is clear, and the wording is possibly confusing.
- F (Allocation) Either in this item or in Section 12 allocation to contracts not covered by PBR methodology in VM-22 needs to be addressed e.g., carve out because reserves calculated on a per policy basis.
- G (Prudent Estimate Assumptions): This sub-section seems more appropriate in Section 4 (or pulled out completely and consolidated within "I. Introduction" or "VM-01" and applied to all PBR methods).
G.2: Suggest replacing “If the results of statistical testing or other testing” with “If the results of the review” to simplify language and avoid possible confusion.

- **Section 4**
  - A.1.b (Guidance Note): The purpose of this guidance note is not clear as these charges would be reflected in the cash flows.
  - A.2: Suggest editing the first sentence to note scope is FIAs and to avoid confusion regarding the term “investment guideline” as follows: “Index crediting strategies for fixed indexed annuities may be grouped for modeling using an approach that recognizes the investment guidelines and objectives of each index crediting strategy.”
  - Given that Section 9 covers hedging, we would suggest considering moving parts of Section 4.A.4 to that section.
  - A.4: Suggest rewording “Future hedging program” to “hedging program with future transactions” to avoid ambiguity.
  - A.4.b.i.b): “Any other purpose” in the last sentence seems overly broad and should be narrowed.
  - A.4.b.i.c): Margins are discussed in a different section, so recommend deleting.
  - A.4.b.i.cj: We believe the company should determine the appropriate margin based on their demonstration of effectiveness. Any guardrails on these undetermined values should be minimal, including as low as 0, subject to the appropriate demonstration of effectiveness. Further, we believe that documentation of effective product management should be contemplated in addition to historical effectiveness.
  - A.5: Unclear why Revenue Sharing is considered for non-variable products, can probably delete.
  - B.1: Section does not specify what the reserve floor shall be (if any) for contracts without cash surrender value.
  - B.3.a: We believe that assets held in the separate account with performance not impacting policyholder benefits should be modeled consistent with how the business is managed.
  - D.4.b: Request clarification around the meaning of “general account index funds.”
  - E.1.b: Suggest deleting “In contrast, for payouts specified at issue, the payout rates modeled should be consistent with those specified in the contract.” as it appears to be covered by E.1.a.
  - E.2: Suggest deleting “may” as there appears to be only option.

- **Section 5**: The wording and titling may need to be tightened due to clarify which items apply to assumed and ceded reinsurance in the text.

- **Section 7**
  - B.3: We recommend removing “pension risk transfer business” from products scoped out of SET certification method. It is unclear why this business would be treated differently from individually issued business for testing intended to capture interest rate risk.
o C.1: As written, the SERT assumes a single premium product given the change of the denominator to the scenario reserve. Alternative product designs (such as longevity swap) could result in unintended results. We recommend maintaining consistency with VM-20 and using a denominator of future benefits (annuity payments, DBs, etc., excluding premium considerations, expenses, etc.).

o C.2.d: Clarification is needed around reference to “significantly different risk profiles.”

o C.3: We request clarification or definition of the term “non-proportional reinsurance.”

o C.3.a.iii: We believe subscript “gy” should be “gn.”

o D.1.a: Does this statement imply a floor reserve of VM-A and VM-C? VM-20 does require the NPR as the floor of the reserve but as written, VM-22 does not require a floor reserve. Recommend removing 1.a. Same statement with the 2.a statement demonstration. This requirement does not apply to the other permitted tests, which seemed counterintuitive.

• Section 9

o Section 4.A.4 (Modeling of Hedges) has some relationship with this section, we request clarification around the applicability of these two areas of hedge guidance.

o A.1: We seek clarification of this text: if a company only hedges indices or separates index crediting from other hedges, does this apply, or does it only apply to any other hedging?

o A.3: The sentence “Prior to reflection in projections, the strategy for future hedge purposes shall be the actual practice of the company for a period of time not less than [6] months.” seems to suggest you would do something other than the actual hedging strategy after [6] months. In this case, what are you assuming for modeling? We suggest clarification of this sentence.

o D.2: Suggest replacing “indexed” with “fixed” since this would apply to all fixed annuities.

• Section 10

o A.7: We would suggest rewording this section to be considerations rather than posed as questions.

o D.8: This section states that “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally.” This text seems to directly contradict Section II. Reserve Requirements 6.H.2 which states “When advantageous, policyholders will commence living benefit payouts if not started yet.” We suggest revising 6.H.2 to align with the text of 10.D.8.

o C (Sensitivity Testing): Suggest updating bullet to “Other material behavior assumptions if relevant to the risks in the product.”

o E.2: Suggest replacing “Risk factors that are not scenario tested but” with “Static assumptions that” to improve clarity in the wording.

o F.1.d (Volatile credit spreads): Suggesting deleting as we are not aware of dynamic credit spreads typically being modeled.

- **Section 11**
  - Specific requirements will require further discussion, particularly what if any industry experience is identified for the SPA. Ideally, updated, and appropriate assumptions should be used for better alignment and to avoid any false positives flagged as an outlier by the SPA.
  - A.4: Terming the segments “mortality (longevity) segments” would be easier to understand than “plus (minus) segments.”
  - B.3.i.c: For PRT an assumption based on a third-party data provider would be better than the industry table to get contract specific mortality assumptions. Is this permitted? The guidance note in A.3 seems to get at this, but it is not clear in B.3.i.c whether this is allowed. This is an important distinction as PRT population can vary from those populations the tables are based upon.
  - B.3.iii: The phrase “When little or no experience or information is available on a business segment” is not included, unlike in (i) and (ii) of the same sub-section. It appears to be the intent that this is the only situation in which this would apply, but it would be helpful to make this explicit.
  - C.1: Both plan and industry data should get weighted for business such as PRT. This text says to blend with prescribed tables, but that might not make sense unless additional experience data was unavailable.
  - C.2: Mortality improvement should be consistent with the underlying tables used, so we would suggest this being based on available experience subject to appropriate guardrails.

- **Section 12:** We believe discussion of allocation of aggregate reserves should be analyzed as part of the field study.

- **Section II: Reserve Requirements**
  - We believe a Fixed Annuity PBR Exemption should be incorporated into draft in a manner consistent with the Life PBR Exemption.
  - 6.H.2: This section states that “When advantageous, policyholders will commence living benefit payouts if not started yet.” This text seems to directly contradict VM-22 Section 6.H.2 which states “contract holder behavior should neither assume that all contract holders act with 100% efficiency in a financially rational manner nor assume that contract holders will always act irrationally”. We suggest revising 6.H.2 to align with the text of 10.D.8.

We appreciate the consideration of our comments and look forward to discussing at a future meeting.

Sincerely,

[Signature]

TO: Reggie Mazyck, NAIC
RE: ARCWG VM-22 Framework Exposure

Dear Mr. Mazyck:

I’m writing to comment on the lack of a true exemption from Annuity PBR as outlined in VM-22.

VM-22 contains a number of exclusion tests, but these differ in meaningful ways from the Life PBR small company exemption (SCE). The primary difference is in the level of complexity required to demonstrate compliance with any of the VM-22 exclusion tests.

The Life PBR SCE is simple by design. It can be completed on a single page using data from financial statements that are readily available. The criteria for this exemption were also simple by design and intentionally did not require any modeling to demonstrate compliance. This exemption was crucial to gaining support for Life PBR from smaller companies with smaller actuarial departments whose primary concerns about PBR came from expense and resource management rather than capital management. For many companies, such an exemption was a prerequisite for their support of PBR during the legislative process.

On the other hand, demonstration of compliance with any of the exclusion tests in VM-22 will likely require a modeling exercise using multiple interest rate scenarios along with supporting documentation that is not meaningfully less than the work and documentation required for those who do not pass an exclusion test. This is hardly the same kind of exemption as is included for Life PBR. Furthermore, it is my understanding that since VM-22 is an amendment to an already adopted valuation manual, it is not required to go through the legislative process and be adopted by state legislatures. If this is the case, I can’t help but wonder if smaller companies would have been supportive of PBR in general had they been aware that their exemption from it could be placed in jeopardy by future edits to the valuation manual.

Given that formulaic reserves have protected the solvency of life insurers for decades in the US, a true exemption should remain available for well-capitalized companies with smaller levels of annuity production who wish to continue to avoid the complexities and expenses associated with model-based reserves.

**The Indexed Universal Life (IUL) (A) Subgroup Exposure**

The Indexed Universal Life (IUL) (A) Subgroup is exposing the options below for public comment.

Please provide comments by Tuesday, July 26 regarding these potential options to address the AG 49-A issues:

(a) attempt a quick fix on the current concern (some companies illustrating uncapped volatility-controlled policies better than capped S&P 500 policies) with a brief revision to AG 49-A; it can be discussed with A committee whether there are plans to address any broader issues with life illustrations;

(b) make no changes to AG 49-A (allow current practices);

(c) attempt to revise AG 49A more extensively to address the current concern and any other identified potential concerns; or

(d) apply a hard cap on various IUL illustration metrics.

There will also be a subsequent opportunity to provide written comments for a period after the August NAIC national meeting.

Please send comments to Reggie Mazyck (RMazyck@NAIC.ORG) by close of business July 26.
July 26, 2022

Mr. Fred Andersen
Chair, IUL Illustration (A) Subgroup
National Association of Insurance Commissioners (NAIC)

Re: The Indexed Universal Life (IUL) Illustration (A) Subgroup Exposure (July 18, 2022)

Dear Mr. Andersen,

The American Academy of Actuaries1 Life Illustrations Work Group (the “Work Group”) is pleased to provide comments to the IUL Illustration (A) Subgroup on the IUL Exposure from the July 18, 2022, meeting of the Subgroup.

As our Work Group discussed the options in the exposure, we realized we don’t have a clear understanding of the regulators’ views on certain matters. We have identified some questions that we encourage the regulators to answer early in the process to help frame the discussion:

1. What, if anything, is the problem that the IUL Subgroup is seeking to resolve? Articulating the problem will help regulators and interested parties identify the appropriate option.
   a. If the regulators are comfortable with current IUL illustration practices, then the option to do nothing may be appropriate.
   b. If the problem is limited to volatility-controlled indices, then a “quick fix” may be appropriate.
   c. If the problem is that Actuarial Guideline (AG) 49-A does not readily accommodate evolving product design, then a more principle-based approach to AG 49-A may be appropriate.
   d. If the problem cannot be addressed within AG 49-A, then a broader effort may be appropriate.

2. Does the “quick fix” option necessitate discussion with the Life Insurance and Annuities (A) Committee as to whether there are plans to address any broader issues with life illustrations, or are there really two options embedded within option (a)?

---

1 The American Academy of Actuaries is a 19,500-member professional association whose mission is to serve the public and the U.S. actuarial profession. For more than 50 years, the Academy has assisted public policymakers on all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues. The Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.
3. What is meant by a “hard cap”? How would it be determined? How would it apply to the product features? Why would a hard cap be appropriate?

4. Which options support consumer understanding of the product features?

5. What information is needed to help the IUL Subgroup develop and evaluate any of the options?

Should the IUL Subgroup decide to apply a “quick fix” to AG 49-A, we suggest referring to the Work Group’s letter dated February 3, 2022, for potential approaches.

The Work Group appreciates the efforts of the Life Actuarial (A) Task Force LATF and IUL Illustration Subgroup to review AG 49-A. If you have any questions or would like to dialogue on the above topics, please contact Amanda Barry-Moilanen, life policy analyst, at barrymoilanen@actuary.org.

Sincerely,

Alicia Carter, MAAA, FSA
Chairperson, Life Illustrations Work Group
American Academy of Actuaries

Mr. Fred Andersen  
Chair, NAIC Indexed Universal Life (IUL) Illustration (A) Subgroup

Re: IUL SG Exposure Jul 18

Mr. Andersen,

Allianz appreciates the opportunity to provide comments on the exposure from the IUL Illustration Subgroup. Our comment letter from February provides relevant information to the discussion on Volatility Control Indexes (VCIs), the additional consumer benefits they can provide, and illustrations practices. As such, Allianz is resubmitting the original letter. Since February, the equity markets, bond markets, and therefore VCIs have generally performed poorly, but that does not materially change the content of the letter. These challenging market conditions highlight the protection inherent in IUL, while also demonstrating the additional value VCIs provide when combined with fixed bonuses.

Thank you for the opportunity to provide these comments.

Regards,

Austin Bichler, FSA, MAAA  
AVP Actuary & Illustration Actuary  
Allianz Life Insurance Company of North America

Mr. Fred Andersen  
Chair, NAIC Indexed Universal Life (IUL) Illustration (A) Subgroup  

Re: IUL Exposure

Mr. Andersen,

Allianz appreciates the opportunity to provide comments on the matters discussed in the LATF IUL Exposure from December, 2021. Allianz offers a variety of allocations with various crediting methods and indexes to consumers. When the cost of hedging any given allocation changes, it is possible to have better historical performance than the S&P500 at a lower cost. In these cases, a company can decide what they would like to do with this excess hedge budget and what the consumer may find most valuable, whether it be higher caps/rates, fixed bonuses, lower charges, or other unique features. The decision on where to provide additional value occurs across all allocations, whether or not they are a Volatility Control Index (VCI). When there are situations where hedging costs are lower and the allocation provides historical outperformance compared to the S&P500, we think it is valuable to the consumer to reflect the additional affordable benefits that are offered within the current restrictions of AG 49-A. Because VCIs are specifically highlighted in the LATF letter and Allianz has offered VCIs for over 8 years, we wanted to provide our perspective on the consumer value of VCIs.

**Allianz History**

Allianz began offering allocations tied to VCIs on its Fixed Index Annuity (FIA) and IUL products in 2013 and 2014 respectively. The benefits of offering an index with a volatility control mechanism include diversification, stability in rate renewal, stability in and strong credit performance, and unique benefits only available with VCIs. Because of these benefits, allocations tied to VCIs offer and have delivered unique value to our policyholders and they are an important part of our index line-up.

VCIs are indexes that have some type of mechanism to control volatility. This mechanism can range from a defined formulaic approach, to active management, to something in between. The VCIs that Allianz offers on our IUL products use a defined formula that rebalances between an equity component and fixed income/cash components on a daily basis. The purpose of this daily rebalancing is to hit a specific volatility target, thus controlling the volatility of the index. Generally speaking, equities are more volatile than fixed income, so the indexes will allocate more heavily to equity in times of low volatility and more heavily to fixed income in times of high volatility.

**Benefits of Volatility Controlled Indexes**

**Diversification**

The combination of equity and fixed income can provide a diversification benefit and the VCIs we offer have both equity and fixed income components, leading to more diversification than a standard equity only index. VCI performance can benefit when either equity or fixed income does well, or if one of the components does not perform well, the other component can offset that low performance and allow the policyholder to still get a credit. This allows the policyholder to experience positive results in many different market environments, not only when the equity market is strong.

Diversification through fixed income can bring risks, and a common question raised about VCIs is will their high allocation to fixed income lead to underperformance in rising interest rate environments and is their good historical performance due to decreasing interest rates over the last 20 years. It is true that fixed income allocations will likely underperform when interest rates rise, but because of the diversification VCIs offer, the overall impact on long term performance of the VCI will vary based on all components of the index, including the...
equity component. The chart below compares the relationship of interest rates with the performance of the first VCI we offered, the Bloomberg US Dynamic Balance Index over the last 20 years.

![Bloomberg US Dynamic Balance vs. 5-yr Treasury](chart)

**Note:** The Bloomberg US Dynamic Balance Index has been active since 2013, index performance before that is based on the underlying components of the index and the prescribed formula used to balance between the components.

While the general trend in rates has been down over the last 20 years, there have been several periods of sustained rate increases or rate spikes, like 2003-2006, 2009, 2017-2018, or 2021. The performance of the Bloomberg US Dynamic Balance Index during those periods is mixed, some really good, some moderate, and some flat. This is because market volatility and the performance of the equity component are material considerations of the VCI performance. In fact, over the last 10 years, interest rates have risen slightly and the performance of the index has been strong, mainly due to lower volatility and strong equity performance.

Because of the diversification offered by VCIs, the performance of the index is also able to weather equity market downturns, like the ones in 2002, 2008/2009, 2018, and 2020. The graph above shows that the VCI did not suffer large losses during those periods. This was due to the volatility control mechanism allocating away from equities when volatility spiked during the market downturns, further enhancing the benefits of diversification of the VCI.

**Stable Rate Renewal**

Volatility is a key driver of hedging costs and market volatility can fluctuate greatly from year-to-year. For a capped S&P500 allocation, changes in market volatility will lead to changes in hedging costs and therefore changes in the offered cap. This can lead to large changes in caps on a year-to-year basis and large changes in the historical lookback used for setting maximum illustrated rates in AG49. By contrast, VCIs target a stable volatility, leading to more stable option costs and therefore more stable affordable participation rates. On a year-to-year basis, the policyholder is less likely to experience large changes in participation rates and large changes in the AG49 lookback. This provides the policyholder a more stable and predictable experience over the life of their contract and creates historical lookbacks that rely less on current market conditions and are more representative of what would have actually been experienced over the historical period.
Stable and Strong Credit Performance

The VCIs we offer target a low and controlled volatility, so the index will increase and decrease more slowly than a higher volatility index, like an equity index. More stable index values lead to more stable credits, which is a benefit for IUL policyholders where product fees are present and timing of high or low credits can impact long term policy performance. Stable credits also better align with IUL illustrations, which do not show the variability of index performance.

The higher stability in credits a VCI can achieve is illustrated below by comparing the distribution of historical performance over the last 20 years between the Bloomberg US Dynamic Balance Index allocation and our capped S&P500 allocation. The analysis uses currently offered caps and participation rates and it can be seen that the distribution of the Bloomberg US Dynamic Balance Index credits are more evenly distributed than the S&P500 credits, which are more barbell shaped and have more instances where the policyholder does not receive a credit.

Note: The Bloomberg US Dynamic Balance Index has been active since 2013, index performance before that is based on the underlying components of the index and the prescribed formula used to balance between the components.

What can also be seen in the analysis above is that Bloomberg US Dynamic Balance Index allocation offers more potential upside than the capped S&P500 allocation. This strong historical performance is seen in the differences in historical lookbacks between the VCI allocations we offer and the capped S&P500, with the VCI allocations outperforming the S&P500 allocation by 2-3% on average.

Allianz started offering allocations tied to the Bloomberg US Dynamic Balance Index on our IUL policies in 2014, so in addition to strong historical lookback performance, we have 7 full years of credits that have been realized by our policyholders. Over that time, our allocation to this VCI has averaged 1.25% higher credits per year than the S&P500 allocation and both of the allocations have performed above the AG49 maximum allowed illustrated credit.

<table>
<thead>
<tr>
<th>Average Realized Credits 2015-2022</th>
<th>AG49 Maximum Illustration Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.77%</td>
<td>8.02%</td>
</tr>
</tbody>
</table>

Note: The analysis above assumes a 1/1/2015 contract issue date, with the version of our IUL product available at that time.
Unique Benefits Available to VCIs
The composition of the VCIs we offer allow us to offer unique benefits to our policyholders. Hedging for the VCIs we offer currently cost less than options for S&P500. We are able to take the hedging savings and offer a variety of benefits for the policyholder to choose from, including higher participation rates, a multiplier bonus, or a fixed bonus, all with a unique lock feature on top of these other benefits.

Our lock feature allows a policyholder to “lock-in” their index performance at any point during their crediting period instead of waiting until their policy anniversary, giving the policyholder a level of control over their policy that they cannot get with any other index. We have seen tremendous interest in this benefit since we introduced it in 2019 and we are only able to offer it because of the stable option costs for VCIs.

Summary
Allianz has offered allocations tied to VCIs since 2013. Our policyholders that have allocated to these indexes have benefited from diversification, stability in renewal rates, stability in and strong credit performance, and features like Index Lock. These policyholders have realized credits that exceed our S&P500 allocations and have been the recipients of additional benefits because of the lower and more stable option costs associated with the VCIs. The VCIs we offer and the additional benefits tied to them make up an important part of our product offering and give our policyholders valuable choice in their allocations. In order to have a fully informed and educated consumer when selecting their allocation choice, we feel that the additional benefits and value VCIs provide should be reflected while still adhering to the current AG 49-A illustration restrictions.

Thank you for the opportunity to provide these comments.

Regards,

Austin Bichler, FSA, MAAA
AVP Actuary & Illustration Actuary
Allianz Life Insurance Company of North America
Dear Mr. Andersen,

We very much appreciate the opportunity to submit the following comments in response to the Indexed Universal Life (IUL) (A) Subgroup Exposure dated July 18th, 2022.

- In February Equitable had provided comments in response to the December 9th, 2021 IUL Exposure, which consisted of (1) a reminder of Equitable’s 2020 proposal and (2) an indication of how the 2020 proposal would relate to illustrations of uncapped volatility-controlled policies. We stated our belief that reconsideration of Equitable’s 2020 proposal would be appropriate if regulators decided that substantive changes to AG 49-A were needed.

We similarly believe that reconsideration of Equitable’s 2020 proposal would be appropriate if regulators decide to pursue option (c) of the latest Exposure, for the same reasons that were stated in our attached February submission. (In viewing the attached Word document, please note that there are two PDFs embedded into the third page containing a more detailed explanation of Equitable’s 2020 proposal.)

- We also believe that option (a) of the latest Exposure should be bifurcated into two separate options,
  o an attempted quick fix to AG 49-A to address the current concern relating to illustrations of uncapped volatility-controlled policies, versus
  o a discussion with A Committee as to whether there are plans to address any broader issues with life illustrations.

- Finally, we feel that we would need to gain a better understanding of option (d) in order to provide any evaluation of it (for example, what illustration metrics would be subjected to a hard cap, how would such a hard cap be applied, and how would this affect the accuracy of depictions of how IUL policies work?).

Thanks again for the opportunity to share our thoughts with you and the other members of the IUL Illustration (A) Subgroup on these issues.

Brian R. Lessing
Senior Director and Actuary
July 26, 2022

THE APPLICATION OF THE LIFE ILLUSTRATIONS MODEL REGULATION TO POLICIES WITH INDEX-BASED INTEREST SOLD AFTER [greater of 5 months after LATF adoption and 3 months after EX/Plenary Adoption*]

Background

The Life Insurance Illustrations Model Regulation (#582) was adopted by the NAIC in 1995. Since that time there has been continued evolution in product design, including the introduction of benefits that are tied to an external index or indices. Although these policies are subject to Model #582, not all of their features are explicitly referenced in the model, resulting in a lack of uniform practice in its implementation. In the absence of uniform guidance, two illustrations that use the same index and crediting method often illustrated different credited rates. The lack of uniformity can be confusing to potential buyers and can cause uncertainty among illustration actuaries when certifying compliance with Model #582.

This guideline provides uniform guidance for policies with index-based interest. In particular, this guideline:

1. Provides guidance in determining the maximum crediting rate for the illustrated scale and the earned interest rate for the disciplined current scale.
2. Limits the policy loan leverage shown in an illustration.
3. Requires additional consumer information (side-by-side illustration and additional disclosures) that will aid in consumer understanding.

Text

1. Effective Date

This Actuarial Guideline shall be effective as follows for all new business and in force illustrations on policies sold on or after [greater of 5 months after LATF adoption and 3 months after EX/Plenary Adoption].

i. Sections 4 and 5 shall be effective for all new business and in force life insurance illustrations on policies sold on or after September 1, 2015.

ii. Effective March 1, 2017, Section 4 and Section 5 shall be effective for all in force life insurance illustrations on policies within the scope of this actuarial guideline, regardless of the date the policy was sold.

iii. Sections 6 and 7 shall be effective for all new business and in force life insurance illustrations on policies sold on or after March 1, 2016.

2. Scope

This Actuarial Guideline shall apply to any life insurance illustration that meets both (i) and (ii), below:

i. The policy is subject to Model #582.

ii. Interest credits are linked to an external index or indices.

ii. The policy offers Indexed Credits.
3. Definitions

A. Alternate Scale: A scale of non-guaranteed elements currently being illustrated such that:

i. The credited rate for each Index Account does not exceed the lesser of the maximum credited rate for the illustrated scale less 100 basis points and the credited rate for the Fixed Account. If the insurer does not offer a Fixed Account with the illustrated policy, the credited rate for each Index Account shall not exceed the average of the maximum credited rate for the illustrated scale and the guaranteed credited rate for that account. However, the credited rate for each Index Account shall never be less than the guaranteed credited rate for that account. The total Indexed Credits illustrated as a percentage of the account value in each Indexed Account does not exceed the maximum total Annualized Percentage Rate of Indexed Credits for the illustrated scale for each Index Account determined in accordance with 4(B) and 4(C), but with the multiple of 120% specified in 4(B) replaced by a multiple of 100%.

ii. If the illustration includes a loan, the illustrated rate credited to the loan balance does not exceed the illustrated loan charge. Policy Loan Interest Credited Rate shall not exceed the illustrated loan charge, Policy Loan Interest Rate. For example, if the illustrated Policy Loan Interest Rate is 4%, the Policy Loan Interest Credited Rate shall not exceed 4%.

iii. All other non-guaranteed elements are equal to the non-guaranteed elements for the illustrated scale.

B. Annual Net Investment Earnings Rate: Gross portfolio annual earnings rate of the general account assets (excluding hedges for Indexed Credits), less provisions for investment expenses and default cost, allocated to support the policy. Charges of any kind cannot be used to increase the Annual Net Investment Earnings Rate.

C. Annualized Percentage Rate of Indexed Credits: The annualized total Indexed Credits divided by the account value used to determine index credits according to the policy features.

B.D. Benchmark Index Account: An Index Account with the following features:

i. The interest calculation is based on the percent change in S&P 500® Index value only, over a one-year period using only the beginning and ending index values. (S&P 500® Index ticker: SPX)

ii. An annual cap is used in the interest calculation.

iii. The annual floor used in the interest calculation shall be 0%.

iv. The participation rate used in the interest calculation shall be 100%.

v. Interest is credited once per year.

vi. Account charges do not exceed the account charges for any corresponding Index Accounts within the policy in any policy year. If Index Accounts with different levels of account charges are offered with the illustrated policy, more than one Benchmark Index Account may be used in determining the maximum illustrated crediting rates for the policy’s Index Accounts, subject to the requirements of 5.D. However, for each Index Account within the policy, only one Benchmark Index Account shall apply. Any rate calculated in 4(B) shall not apply for an Index Account if the account charges for the applicable Benchmark Index Account exceed the account charges for that Index Account in any policy year. Account charges include all charges applicable to an Index Account, whether deducted from policy values or from premiums or other amounts transferred into such Index Account.

vii. Additional amounts credited are not less than the additional amounts credited for any corresponding Index Accounts within the policy in any policy year. Any rate calculated in 4(B) shall not apply for an Index Account if the additional amounts credited for the applicable Benchmark Index Account are less than the additional amounts credited for that Index Account in any policy year. Additional amounts...
include all credits that increase policy values, including but not limited to experience refunds or bonuses, that are not linked to an index or indices.

viii. There are no limitations on the portion of account value allocated to the account.

C.E. Fixed Account: An account where the credited rate is not tied to an external index or indices, there are no Indexed Credits.

F. Index Account: An account where some or all of the amount credited are Indexed Credits.

G. Indexed Credits: Any interest credit, multiplier, factor, bonus, charge reduction, or other enhancement to policy values that is linked to an index or indices. Any additional amounts credited to the policy resulting from an annual floor on an Index Account are included.

H. Hedge Budget: For each Index Account, the total annualized amount assumed to be used to generate the Indexed Credits of the account, expressed as a percent of the account value in the Index Account. This total annualized amount should be consistent with the hedging program of the company.

I. Loan Balance: Any outstanding policy loan and loan interest, as defined in the policy.

J. Policy Loan Interest Rate: The current annual interest rate as defined in the policy that is charged on any Loan Balance. This does not include any other policy charges.

K. Policy Loan Interest Credited Rate: The annual interest rate is tied to an external index or indices credited that applies to the portion of the account value backing the Loan Balance, as defined in the policy.

i. For the portion of the account value in the Fixed Account that is backing the Loan Balance, the Policy Loan Interest Credited Rate is the applicable annual interest crediting rate, as defined in the policy.

ii. For the portion of the account value in the Fixed Account that is backing the Loan Balance that is in an Index Account, the Policy Loan Interest Credited Rate is the total percentage rate of Indexed Credits for that account, as defined in the policy.

4. Illustrated Scale

The credited rate total Annualized Percentage Rate of Indexed Credits for the illustrated scale for each Index Account shall be limited as follows:

A. Calculate the geometric average annual credited rate for each applicable Benchmark Index Account for the 25-year period starting on 12/31 of the calendar year that is 66 years prior to the current calendar year (e.g., 12/31/1949 for 2015 illustrations) and for each 25-year period starting on each subsequent trading day thereafter, ending with the 25-year period that ends on 12/31 of the prior calendar year. Calculate the value of the replicating option trades to provide the total Indexed Credits for the Benchmark Index Account over the preceding calendar year, based on the Black-Scholes formula using the following inputs calculated on each trading day:

i. Average closing implied volatility for 12-month, at-the-money S&P 500 call options

ii. Average closing implied volatility for out-of-the-money 12-month S&P 500 call options with a normalized strike price equal to the currently declared cap

iii. Average dividend yield on the S&P 500

iv. Average 12-month LIBOR or another appropriate interest rate measure

v. If the insurer offers an applicable Benchmark Index Account with the illustrated policy, the illustration actuary shall use the current annual cap for the applicable Benchmark Index Account in 4 (A).
ii.vi. If the insurer does not offer an applicable Benchmark Index Account with the illustrated policy, the illustration actuary shall use actuarial judgment to determine a hypothetical, supportable current annual cap for a hypothetical, supportable Index Account that meets the definition of a Benchmark Index Account, and shall use that cap in 4 (A).

B. For each applicable Benchmark Index Account the total Indexed Credits illustrated as a percentage of the account value in the Index Account shall not exceed 120% of the minimum of (i) and (ii):

iii. the value calculated in 4 (A) the arithmetic mean of the geometric average annual credited rates calculated in 4 (A) shall be the maximum credited rate(s) for the illustrated scale.

ii. the greater of 5% and the Annual Net Investment Earnings Rate.

C. For any other Index Accounts using other equity, bond, and/or commodity indexes, and/or using other crediting methods, the illustration actuary shall use actuarial judgment to determine the maximum credited rate for the illustrated scale. The determination shall Account that is not the Benchmark Index Account in 3 (D), the total Indexed Credits illustrated as a percentage of the account value in the Index Account shall not exceed the minimum of (i) and (ii):

i. The maximum Indexed Credits for the Benchmark Index Account calculated in 4 (B).

B.ii. Total Indexed Credits that reflect the fundamental characteristics of the Index Account as related to the Black-Scholes valuation formula, including realized volatility, implied volatility, volatility targets (if applicable), embedded fees (if applicable), deduction of an interest rate component (if applicable), dividend participation (if applicable) and any other factors that may apply. The illustration actuary shall use actuarial judgement to determine this value using Black Scholes methodology in a manner consistent with 4(A) and 4(B) where appropriate. and the parameters shall have the appropriate relationship to the expected risk and return of the applicable Benchmark Index Account. In no event shall the credited rate for the illustrated scale exceed the applicable rate calculated in 4 (B).

D. At the beginning of each calendar year, the insurer shall be allowed up to three (3) months to update the credited rate for each Index Account in accordance with 4 (B) and 4 (C).

5. Disciplined Current Scale
   The earned interest rate for the disciplined current scale shall be limited as follows:

A. If an insurer engages in a hedging program for index-based interest Indexed Credits, the assumed earned interest rate underlying the disciplined current scale for the policy, inclusive of all general account assets, both hedge and non-hedge assets, that support the policy, net of default costs and investment expenses (including the amount spent to generate the Indexed Credits of the policy) shall not exceed 145:

i. the Annual Net Investment Earnings Rate, plus

ii. 45% of the Hedge Budget minus any annual floor. net investment earnings rate (gross portfolio earnings less provisions for investment expenses and default costs) of the general account assets (excluding

These amounts should be adjusted for timing differences to ensure that fixed interest is not earned on the hedge cost. The assumed return on hedges for index-based credits allocated to support shall only be used in the disciplined current scale testing to support the illustrated Index Credits in the policy.

Guidance Note: The above approach does not stipulate any required methodology as long as it produces a consistent limit on the assumed earned interest rate underlying the disciplined current scale.
A-B. If an insurer does not engage in a hedging program for index-based interest Indexed Credits, the assumed earned interest rate underlying the disciplined current scale shall not exceed the annual net investment earnings rate of the general account assets allocated to support the policy Annual Net Investment Earnings Rate.

B-C. These experience limitations shall be included when testing for self-support and lapse-support under Model #582, accounting for all illustrated benefits including any illustrated bonuses that impact the policy’s account value.

C-D. If more than one Benchmark Index Account is used for an illustrated policy, each set of Index Accounts that correspond to each Benchmark Index Account must independently pass the self-support and lapse-support tests under Model #582, subject to the limitations in 5 (A), (B), and (C). All experience assumptions that do not directly relate to the Index Accounts as to expenses, mortality, investment earnings rate of the general account assets, lapses, and election of any Fixed Account shall equal the assumptions used in the testing for the entire policy.

6. Policy Loans

If the illustration includes a loan, the illustrated rate credited to the loan balance Policy Loan Interest Credited Rate shall not exceed the illustrated loan charge Policy Loan Interest Rate by more than 100 basis points. For example, if the illustrated Policy Loan Interest Rate is 4%, the Policy Loan Interest Credited Rate shall not exceed 5%.

7. Additional Standards

The basic illustration shall also include the following:

A. A ledger using the Alternate Scale shall be shown alongside the ledger using the illustrated scale with equal prominence.

B. A table showing the minimum and maximum of the geometric average annual credited rates calculated in 4 (A).

C-B. For each Index Account illustrated, a table showing actual historical index changes and corresponding hypothetical interest rates Indexed Credits using current index parameters for the most recent 20-year period.
Fred,

Thank you for the opportunity comment on the four potential options for handling the identified issue with Indexed Universal Life illustrations.

We believe that the current state of Indexed UL illustrations warrants a quick and comprehensive response from the Subgroup. As the letter from the Coalition of Concerned Insurance Professionals pointed out in February (attached), Indexed UL illustrations using non-BIA strategies with fixed interest bonuses can generate illustrated income in excess of 60% higher than BIA strategies. This is, in our view, entirely inconsistent with the intent of regulators in crafting AG 49-A.

The gamesmanship currently occurring in illustrations is similar in effect and pervasiveness to the buy-up caps and multipliers that proliferated after AG 49 and resulted in AG 49-A. However, it is important to note that this time the methodology is fundamentally different. Rather than increasing the option budget in order to augment illustrated performance (which is what buy-up caps and multipliers did), life insurers are now using essentially the opposite strategy by:

1. Using indices with lookback-based illustrated option profits far in excess of the BIA;
2. Reducing the actual option budget so that the lookback rate for the non-BIA account matches the BIA;
3. Deploying the savings in a fixed interest bonus that is added to the illustrated rate and loan arbitrage.

The net effect is non-BIA account options that illustrate significantly better than the BIA but, in the real world, will very likely perform worse. Often, life insurers set these strategies as the default allocation in their illustration software in order to maximize their competitive positioning. This is not what was intended by AG 49-A – nor is it beneficial for consumers or even defensible under the arguments put forth previously by industry.

As a result, Option B is simply not an option. Amongst life insurers, the issue at hand is crystal clear; everyone is well aware of exactly what is going on. The majority of top Indexed UL sellers are already using precisely this strategy in their products, and to great effect. In our view, this latest variant of Indexed UL illustration gamesmanship is more aggressive and puts clients in a worse position than the previous attempts. This must be addressed. To not do so would be inconsistent with previous Subgroup inquiries.

Options A, C and D imply tradeoffs that don’t actually exist. A simple solution (Option A) need not be targeted only to the current issue. A proactive solution (Option C) need not require extensive modifications to the guideline. A “hard cap” (Option D) need not exist in isolation.

The best potential solutions would satisfy all three Options – simple and proactive, with “hard caps” to avoid edge cases and ambiguity. Fortunately, these solutions exist and have been presented previously to the Subgroup by several parties (including various life insurers) over the past eight years.

Considering that the complex, reactive and ambiguous solutions promoted by industry have resulted only in more illustration warfare and repeated regulatory inquiries, it’s time to dust off the alternative proposals and give them serious consideration.

Mr. Mike Boerner  
Chair, NAIC Life Actuarial Task Force (LATF)

Mr. Fred Andersen  
Chair, NAIC Indexed Universal Life (IUL) Illustration (A) Subgroup (IUL Subgroup)

Dear Fred,

Securian Financial respectfully submits these comments in response to the NAIC IUL Illustrations (A) Subcommittee request for comments on AG49-A.

To reiterate the main points of Securian’s comment letter in February:

- AG49-A was successful for products that charge for multipliers and/or buy-up accounts as they are illustrating substantially similar to those products without the additional charges.
- There is nothing inherently wrong with fixed account value bonuses, proprietary indices, or the combination of them.
- Securian Financial has deep concerns that the amount of leverage being illustrated on non-BIA Indexed accounts is not consistent with the intent of AG49/AG49-A or what LATF would expect of these type of illustrations.

Securian Financial believes that option (a) of the July request for comment is the most desirable of the choices presented. There are several straightforward ways to change AG49-A to make it clearer/enforce that the BIA guardrails apply to all illustrated indexes. We would like the language below to be added to AG49-A as a starting point for the conversation on how the subgroup could approach option (a) in the July requests for comments.

**Recommended Changes**

We would like to recommend changes to AG49-A 4C by adding condition (iii) to limit the maximum amount of leverage illustrated to that of the BIA:

C. For any other Index Account that is not the Benchmark Index Account in 3 (D), the Annual Rate of Indexed Credits illustrated as a percentage of the account value in the Index Account prior to the deduction of any charges used to fund a Supplemental Hedge Budget shall not exceed the minimum of (i), (ii) and (iii):

   i. The Annual Rate of Indexed Credits for the Benchmark Index Account calculated in 4 (B) plus the Supplemental Hedge Budget for the Index Account.

   ii. The Annual Rate of Indexed Credits reflecting the fundamental characteristics of the Index Account and the appropriate relationship to the expected risk and return of the Benchmark Index Account. The illustration actuary shall use actuarial judgment to determine this value using lookback methodology consistent with 4 (A) and 4 (B) (i) where appropriate.
iii. The lesser of (a) and (b) multiplied by the Annual Rate of Index Credits for the Benchmark Index Account, calculated in 4B, divided by (b); plus, the supplemental hedge budget:
   a) The Hedge Budget of the Indexed Account
   b) Hedge Budget of the Benchmark Indexed Account.

The spreadsheet attached uses the same parameters as was used in 2020 but with two more examples to show how the proposed change would impact several index designs and the added rows for the new 4(c)iii and the resulting options profit being illustrated. Focus your attention on Column E and note that without 4(c)(iii), the illustrated leverage (option profit) as seen on Row 29 would be 155%.

Respectfully,

Seth Detert, Securian Financial

Mr. Mike Boerner  
Chair, NAIC Life Actuarial Task Force (LATF)  

Mr. Fred Andersen  
Chair, NAIC Indexed Universal Life (IUL) Illustration (A) Subgroup (IUL Subgroup)  

Dear Fred,  

Securian Financial respectfully presents these comments in response to the NAIC IUL Illustrations (A) Subcommittee request for comments on the findings from the Q3 Post AG49-A IUL survey.  

Securian believes the Post AG49-A IUL survey demonstrates that AG49-A accomplished one of the main goals set forth by the Subcommittee:  

- That products with charged for multipliers and/or buy-up accounts illustrate substantially similar to those products without the additional charges.

However, with new developments in the industry AG49-A appears to have fallen short of the second stated goal:  

- That within an illustration there is consistent treatment of policy features such as multipliers, index bonuses, participating loan crediting, and non-benchmark indices across the industry.

Specifically, after AG49-A, as noted by the request for comment letter, we are seeing an increase in the utilization of volatility-controlled indices in conjunction with fixed bonuses. Carriers are utilizing this combination to drive meaningfully higher illustrated results.

In direct contrast to the intent of AG49-A, carriers are illustrating much more aggressively with these volatility-controlled indices relative to their own S&P 500 BIA accounts.

Securian does not believe there is anything inherently wrong with fixed account value based bonuses. Fixed account value bonuses are not specific to IUL and they have been part of the individual life products for decades. In addition, fixed bonuses were discussed rather extensively during the drafting of AG-49A and from those discussions LATF determined it was appropriate to illustrate them, in hopes of furthering consumer understanding on the differences between products.

Volatility-controlled indices have also been in the insurance industry for years. They have been prevalent in Fixed Index Annuities for a decade (or more) and there have been a small amount of them available for on IUL contracts for the last 5 to 10 years. We are seeing an increase in the availability and utilization of volatility-controlled index in the industry and Securian supports that direction. Volatility-controlled indexes provide options for our clients that can reasonably provide more stable index returns over a long period of time.

However, Securian does think that the current practice of how volatility-controlled indexes are being illustrated in the industry does not meet the intention of AG49 or AG49-A and should be addressed in
the very near future. Specifically, the 145% limit should be applied to all accounts, not just the BIA account. Let me explain further.

Within AG-49 the determination of the maximum illustrated rate for the BIA account is limited to 145% of the Annual Net Investment Earnings Rate used to support the index. We think this guardrail should also be applied to non-BIA accounts. What we are seeing in the industry can be illustrated by a simple example:

- Let’s consider a carrier that has a 4% Annual Net Investment Earnings Rate and they spend that amount on the BIA account. This translates to a maximum illustrated rate of 4% * 1.45% = 5.8%.
- The carrier also has a volatility-controlled index that costs 3% to hedge which allows the carrier to offer a 1% fixed bonus on that indexed account to get a total 4% cost.
- The volatility-controlled index’s 30 year look back rate is at or above the maximum BIA rate of 5.8% in this example. Most carriers are then illustrating the volatility-controlled index at 5.8%.
- By illustrating the volatility-controlled index at 5.8% they are illustrating a hedge payoff of (5.8%/3%) = 1.93% which is excess of the 1.45% guardrail of the BIA.
- The increased illustrated hedging payoff in excess of the 145% BIA guardrail is what Securian believes is the main driver of higher illustrated values for volatility-controlled indices.
- If volatility-controlled indices were limited in illustrating a maximum of 1.45% hedge payoff you would get a max illustrated rate in this example of 3%*1.45% = 4.35%.
- Using the example above with an adjustment to AG49-A to limit the hedge payoff to 145% of the volatility-controlled index you would get a total crediting rate of 4.35% plus the 1% fixed bonuses for a total crediting rate of 5.35% versus what is being currently being illustrated in the industry of 5.8% plus a 1% fixed bonus for a total crediting rate of 6.8%.

Securian believes there are several ways to change AG49-A to make it clearer/enforce that the 145% guardrail applies to all illustrated indexes. If desired by LATF we are ready to work with our industry peers to put forth draft language to address what we see is the crux of the concern presented by LATF from the findings of the post AG49-A survey.

Respectfully,

Seth Detert, Securian Financial

NAIC Proceedings – Summer 2022

Attachment Thirty-Six
Life Actuarial (A) Task Force
8/8–9/22


July 26, 2022

Mr. Mike Boerner  
Chair, NAIC Life Actuarial Task Force (LATF)

Mr. Fred Andersen  
Chair, NAIC Indexed Universal Life (IUL) Illustration (A) Subgroup (IUL Subgroup)

via email to RMazyck@naic.org

Re.: IUL Exposure

Dear Messrs. Boerner and Andersen:

The Transamerica Companies ("Transamerica") appreciate the opportunity to provide comments on the exposed options for the work of the IUL Subgroup and potentially other NAIC committees. Transamerica is a leading provider of IUL and had the top-selling individual IUL product across all channels in 2021, according to Wink, Inc.\(^1\)

From our standpoint, AG49-A has successfully remediated concerns with illustrations of multipliers and certain other IUL product design features. More recently, we understand that questions have emerged around illustrations for products with uncapped volatility-controlled indices and fixed bonuses. Although we regard these features as having somewhat less impact on illustrations than multipliers, we can support an update to AG49-A to address these features. It should be noted that Transamerica does not currently sell a product with an uncapped volatility-controlled index and a fixed bonus.

Of the four options in the exposure, Transamerica supports option (a), the "quick fix" approach. For example, consideration could be given to requiring each index account to separately pass both the self-support and lapse support tests as prescribed under Model #582. We can also support A Committee consideration of a longer-term, multi-year effort to overhaul illustrations for all fixed life insurance products, presumably involving the re-opening of the model. We believe such an effort should address illustrations holistically across products rather than taking a piecemeal approach.

We appreciate the work of LATF and the IUL Subgroup in addressing concerns related to IUL illustrations.

Sincerely,

Andrew DeMarco  
Head of Life Solutions  
Transamerica

July 26, 2022

Mr. Fred Andersen  
Chair, NAIC Indexed Universal Life (IUL) Illustration (A) Subgroup

Western & Southern Financial Group, Inc. (“Western & Southern”) appreciates the opportunity to comment on the Indexed Universal Life (IUL) (A) Subgroup (“IUL Subgroup”) exposure of options to address AG 49-A.

Western & Southern does not have concerns with IUL products incorporating volatility-controlled indexes, nor does it have concerns with IUL products including fixed interest rate bonuses. However, Western & Southern believes the current approach of pairing a volatility-controlled index with a fixed interest rate bonus and having that combination illustrate better than capped S&P 500 benchmark indexed account (BIA) policies falls outside the intent of AG49-A.

Thus, Western & Southern supports option A to “attempt a quick fix on the current concern (some companies illustrating uncapped volatility-controlled policies better than capped S&P 500 policies) with a brief revision to AG 49-A.” Western & Southern notes that the American Academy of Actuaries Life Illustrations Work Group presented two viable options to address the issue within its February 3, 2022 comment letter. Western & Southern supports additional consideration of those two options and the expeditious implementation of whichever one (or a newly identified alternative) that the IUL Subgroup deems to be most effective in addressing the current issue. If the IUL Subgroup decides to take additional time to analyze options C or D, Western & Southern encourages it also to move forward with option A concurrently to ensure a level playing field and the protection of consumers.

Western & Southern appreciates the IUL Subgroup’s continued review of AG49-A; thank you for the opportunity to comment.

Respectfully,

Ryan Richey, FSA, MAAA  
Vice President, Product Actuarial
The Indexed Universal Life (IUL) Illustration (A) Subgroup met July 18, 2022. The following Subgroup members participated: Fred Andersen, Chair (MN); Ted Chang (CA); Manny Hidalgo (CT); Mike Yanacheak (IA); Vincent Tsang (IL); Derek Wallman (NE); Bill Carmello (NY); Peter Weber (OH); Maribel Castillo, Darlene Plyler, and Heike Ulrich (TX); Shelley Wiseman (UT); and Craig Chupp (VA).

1. **Exposed Options for Revising AG 49-A**

Mr. Andersen said the Subgroup last met on Feb. 24. He suggested that three meetings will be necessary to decide how to address the issues that have arisen since the 2020 adoption of AG XLIX-A—*The Application of the Life Illustrations Model Regulation to Policies with Index-Based Interest to Policies Sold on or After December 14, 2020* (AG 49-A). He said there will be a two-step approach to addressing the issues. The first step will be to publicly expose a set of options on which all parties will be asked to comment before the close of business July 26. He said those comments will be considered during the Life Actuarial (A) Task Force meeting at the Summer National Meeting. He said the second step will be to continue discussion during a Subgroup meeting after the Summer National Meeting. He said review of the compliance of indexed universal life (IUL) illustrations with AG 49-A requirements showed that the guideline has been effective in addressing multipliers and buy-up accounts, the product features that were the prior concern. He said the new issue of concern is that companies are illustrating the combination of uncapped volatility-controlled funds and a fixed bonus more favorably than illustrations based on a traditional capped Standard and Poor’s 500 index (S&P 500).

Mr. Andersen said the options for the Subgroup to consider implementing to address the concern are:

- Attempt a quick fix on the current concern (some companies illustrating uncapped volatility-controlled policies better than capped S&P 500 policies) with a brief revision to AG 49-A. It can be discussed with the Life Insurance and Annuities (A) Committee whether there are plans to address any broader issues with life illustrations.
- Make no changes to AG 49-A (and allow current practices).
- Attempt to revise AG 49-A more extensively to address the current concern and any other identified potential concerns.
- Apply a hard cap on various IUL illustration metrics.

Birny Birnbaum (Center for Economic Justice—CEJ) said that the last two options have been tried previously with no success. He said companies have been able to easily game AG 49-A. He asked why Mr. Andersen expects a different outcome if one of those options is chosen. Mr. Andersen said he included those options because he wanted to give a full slate of workable options. He said there are pros and cons to each of the four options, including those mentioned by Mr. Birnbaum, that will likely be considered.

There was no objection from Subgroup members to exposing the options for addressing the AG 49-A concerns (Attachment Thirty-Nine-A) for an eight-day public comment period ending July 26.

Having no further business, the Indexed Universal Life (IUL) Illustration (A) Subgroup adjourned.

https://NAICSupportStaffHub/Member Meetings/2022 NAIC Meetings/Spring National Meeting/Committee Meetings/LIFE INS and ANNUITIES (A) COMMITTEE/Life Actuarial (A) TF/IUL SG/07 18/July 18 Minutes.docx

© 2022 National Association of Insurance Commissioners
The Indexed Universal Life (IUL) (A) Subgroup Exposure

The Indexed Universal Life (IUL) (A) Subgroup is exposing the options below for public comment.

Please provide comments by Tuesday, July 26 regarding these potential options to address the AG 49-A issues:

(a) attempt a quick fix on the current concern (some companies illustrating uncapped volatility-controlled policies better than capped S&P 500 policies) with a brief revision to AG 49-A; it can be discussed with A committee whether there are plans to address any broader issues with life illustrations;

(b) make no changes to AG 49-A (allow current practices);

(c) attempt to revise AG 49A more extensively to address the current concern and any other identified potential concerns; or

(d) apply a hard cap on various IUL illustration metrics.

There will also be a subsequent opportunity to provide written comments for a period after the August NAIC national meeting.

Please send comments to Reggie Mazyck (RMazyck@NAIC.ORG) by close of business July 26.

</table>
"Other Derivative Instruments" row: Unlike the "Derivative Instruments linked to Equity-Like Instruments", the "Other Derivative Instruments" row requests entries for the attribution fields. This is because while "Derivative Instruments linked to Equity-Like Instruments" may be considered Equity-Like Instruments, this may not necessarily be the case for derivatives linked to underlying assets other than equities or similar instruments. Therefore, the intention is that such assets would be subject to attribution analysis requirements.

### Additional Commentary

- **Section 5a: Sensitivity Test**
  - Cash Flow Testing: Present Value of Market Value of Surplus under Level Scenario
  - Present Value of Market of Net Spread Benchmark

---

¹ "Percentage of Assets with Reduced Spread" is the percentage of asset amount for which the net spread must be reduced to comply with the cap at the Investment Grade Net Spread Benchmark.

² "Net Spread Reduction" means the aggregate net spread reduction in each asset category as a result of capping individual assets at the Investment Grade Net Spread Benchmark.

³ Intended to measure the impact of asset adequacy testing in each scenario to address the impact of capping individual assets at the Investment Grade Net Spread Benchmark.
